Title: Developmental increase in cortical myelination and internodal length variability in the mouse neocortex

Authors: *E. PAMA, K. A. EVANS, P. HUMPHREYS, R. T. KÁRADÓTTIR;
Wellcome Trust - Med. Res. Council Cambridge Stem Cell Inst., Univ. of Cambridge, Cambridge, United Kingdom

Abstract: Myelin is essential for cognitive functioning and its loss or damage is associated with a number of neurological disorders and mental illnesses [1]. Alternations in myelination are increasingly being implicated as a mechanism for learning. Despite the importance of myelin, age-related myelination changes are poorly understood. Increases in white matter volume have been observed across several brain regions in childhood and adolescence, both in humans and other species[2,3,4]. However, while many studies investigate myelination in rodent models, the exact nature of developmental myelination changes in mice is still unclear. Importantly, differential myelination patterns have been found in distinct cortical layers within the mouse brain[5]. In addition to the overall myelination pattern, various other structural features such as the amount and length of internodes along axons may potentially affect conduction speed and change over time. In the peripheral nervous system, a functional relationship between internodal distance and conduction speed has been demonstrated and internodal length increases throughout development[6]. The question arises whether the same pattern occurs in the central nervous system (CNS). Therefore, we investigated myelin distribution and structure in the mouse brain neocortex at various time points during development (*p0-p118*). In addition to overall myelination we studied specific myelin features such as internodal length. We used immunohistochemistry to stain for myelin changes and by using high-resolution confocal imaging we were able to quantify cortical myelination and internodal distances. Our preliminary results indicate an increase in cortical myelination over time: a gradual increase in all cortical layers was observed, with no myelination present in the first week. While we indeed observed higher myelin density in deeper layers, our results suggest that the variability of internodal length (instead of overall internodal

length) continues to increase during the developing CNS. In summary, these results suggest that the development of complex neural circuits may be accompanied by characteristic, staged changes in myelination, highlighting the potential role of myelin in network synchronisation.

Title: Characterization of an *In vivo* tool to study oligodendrocyte metabolic support to neurons

Authors: *T. PHILIPS, B. M. MORRISON, J. D. ROTHSTEIN;
Dept. of Neurology, Brain Sci. Inst., Johns Hopkins Univ., Baltimore, MD

Abstract: Numerous studies have shown that neuronal metabolism is highly dependent on the metabolic support they receive from their neighboring glial cells. Astrocytes and oligodendrocytes are now well established as cells important for providing metabolic support to neurons. One particular pathway involved is mediated by the monocarboxylate transporters (MCTs) that transport lactate, pyruvate and ketone bodies across the plasma membrane, to be taken up by neurons as important alternative metabolic substrates. We have previously shown that one of these MCTs, MCT1, is strongly expressed by oligodendrocytes. Local delivery of

MCT1-shRNAs targeting oligodendrocytes leads to neuron death and axon degeneration, suggesting oligodendrocytes provide essential metabolic support to neurons.
In the current study we have developed new tools to characterize MCT protein expression in the CNS and their metabolic supportive role to neurons. Using newly generated, highly specific antibodies for MCT1 as well as using a MCT1-GFP expressing tag-in reporter mouse, we found that in addition to oligodendrocytes, MCT1 was expressed in astrocytes, endothelial cells and ependymal cells throughout both human and mouse CNS regions. However, antibody expression cannot define the relative quantitative role for this transporter in the various glial and endothelial cells. In order to better understand the MCT1 mediated metabolic supportive role in oligodendrocytes, we developed a conditional knockout mouse for MCT1, in which MCT1 exon2 is inserted between two loxP sites. When crossed with oligodendrocyte Mogi-Cre mice, homozygous MogiCre::MCT1loxP/loxP mice showed a >90% reduction of MCT1 protein in myelin preps of CNS tissue. Interestingly, these mice did not develop gross pathological or behavior abnormalities up to one year of age. On the other hand, mice which were knockout (KO) for MCT1 on one allele and had a complete knockout specifically in oligodendrocytes on the other allele (MogiCre::MCT1loxP/KO) developed strong pathology (astrogliosis, degeneration) at six months of age in different brain regions. Heterozygous MCT1 KO control mice did not show any behavior or pathological abnormalities. This data suggests that oligodendrocyte loss of MCT1 under normal physiological conditions is insufficient to cause severe neuronal injury but that loss of MCT1 in other cell types, in addition to oligodendrocytes, contributes to a highly significant brain pathology. We are currently assessing the behavioral consequences associated with this pathology as well as trying to understand how other cell types like astrocytes and endothelial cells are involved in this injury response.

Title: Vesicular trafficking in Schwann cell development and myelination

Authors: *B. ABDELMESIH, C. EYERMANN, C. MELENDEZ-VASQUEZ;
Hunter Col., New York, NY

Abstract: Myelination in the peripheral nervous system is carried out by Schwann cells (SC), which enwrap and insulate axons facilitating rapid transmission of nerve impulses. Non-muscle myosin II (NMII), an actin-binding motor protein, is a key regulator of cytoskeleton dynamics necessary for interactions between SC and axons and normal myelin formation. NMII activity is regulated by the phosphorylation of its regulatory light chain (MLC). Previous work from our laboratory indicated that one of the kinases that phosphorylates MLC, myosin light chain kinase (MLCK) is required for normal SC myelination. Knockdown of MLCK in SC results in prominent accumulation of large vesicles and increased autophagic and lysosomal protein expression suggesting that MLCK activity is necessary for proper protein trafficking. We now show Rab7+ vesicles accumulate in SC in the absence of MLCK activity. Rab7 is a GTPase that regulates late endosomal trafficking and lysosomal biogenesis. We find this effect only in the presence of MLCK inhibitor and not with inhibitors of NMII phosphorylation or motor activity. Furthermore, we show significantly increased co-localization between Rab7 and Rab9. Rab9 is a GTPase important for transporting lysosomal hydrolases between the trans golgi network and late endosomes. Inhibition of MLCK and accumulation of Rab7-Rab9+ vesicles may suggest that lysosomal enzymes are mislocalized. Currently, we are investigating the mechanism by which MLCK activity is required for proper Rab7 trafficking, and how Rab7 function may be required for myelin proteins to be delivered to the plasma membrane to achieve normal myelination.

Title: Investigating oligodendrocyte axonal preference in the mammalian central nervous system. A whole-tissue high-resolution approach.

Authors: *E. M. FLORIDDIA, C. BELLARDITA, P. LÖW, O. KIEHN, G. CASTELO-BRANCO;
Karolinska Institutet, Stockholm, Sweden

Abstract: Oligodendrocytes (OLs) are the myelinating cells in the central nervous system (CNS). They insulate axons affecting the conduction speed of action potentials, making OLs very important actors in neurological functions and disorders. Single-cell RNA-Seq studies performed in our laboratory show that the CNS comprises 12 subpopulations belonging to the OL lineage, spanning from oligodendrocyte precursor cells (OPCs) to mature OLs (MOLs). These data also highlight transcriptional differences among myelinating OL subpopulations. However, the impact of OL transcriptional heterogeneity on their functionality is unclear. One important and unanswered functional question is how OLs decide what neurons to myelinate. Also whether certain OL subpopulations specifically myelinate only certain type of axons is unexplored. To address these questions, we use whole-tissue high-resolution imaging (CLARITY method). This approach allows us to acquire sufficiently detailed and large 3D images to analyze the intricate and heterogeneous morphologies of OLs and interactions with neurons in the intact cortex and spinal cord. We will fate map OPCs, label OL subpopulations with newly found-specific markers, and describe their interaction with different kind of neurons via CLARITY-optimized light-sheet (COLM) or confocal microscopy. We will discriminate neurons based on location (white and grey matter), morphology (long- or short-distant projecting), and activity (excitatory or inhibitory). Therefore, we will be able to correlate OL and neuronal types at high resolution and for the entirety of the OL and neuronal processes extension. We will analyze the acquired images to obtain 3D visualizations of OL morphologies, OLs-neurons interactions, and quantification of internodes number and length. Importantly, our approach does not rely on the assumption that the tissue is homogeneous, as 3D reconstruction based on tissue sections does. In conclusion, we aim to unveil the OL axonal preference in the mammalian CNS, shedding light on the fine-tuned cellular dynamics and functional heterogeneity of the OL lineage.

Title: Preservation of Schwann cell identity *In vitro* through bone morphogenetic protein signaling

Authors: *Y.-S. CHAN, Y. P. TSUI, D. K. Y. SHUM;
Sch. of Biomedic. Sci., Fac. Med., Univ. Hong Kong, Hong Kong, China

Abstract: In the injured nerve environment, Schwann cells switch on an axon-supportive program that improves nerve regeneration and functional recovery. We therefore devised a protocol to derive Schwann cells from bone marrow stromal cells (Shea et al, Exp Neurol, 2010). In standard cultures of Schwann cells extracted from sciatic nerves of neonatal rats, we serendipitously observed expression of Olig2, the obligate transcription factor for oligodendrogenesis, as of 25 DIV; these Olig2-positive cells showed polydendrocytic morphology reminiscent of oligodendrocyte precursors. Increase in Olig2-positive cells was accompanied by decline in p75-immunopositivity among continuing cultures of the Schwann cells. We then hypothesized that the peripheral nerve environment harbours factors that preserve Schwann cell identity. In support of this, co-cultures of 25-DIV Schwann cells with neurons purified from dorsal root ganglia (DRG, E15) led to decline in incidence of Olig2-positive oligodendrocyte precursor cells. Our search for factors that suppress Olig2 expression found BMP4-immunoreactivity localized to the DRG neurons. Supplementation of BMP4 to 25-DIV Schwann cell cultures suppressed Olig2 expression but preserved p75 expression and the spindle morphology of Schwann cells. Preservation of Schwann cell identity *in vitro* therefore requires signalling cues, including BMP4, presented by peripheral neurons.

Title: Human Schwann cell senescence is not prevented by ectopic expression of human telomerase reverse transcriptase

Authors: *N. D. ANDERSEN[1], B. KUO[1], G. PIÑERO[1], K. RAVELO[1], P. RAI[2], P. MONJE[1]; [1]The Miami Project to Cure Paralysis, Dept. of Neurolog. Surgery, [2]Dept. of Med., Univ. of Miami Miller Sch. of Med., Miami, FL

Abstract: Isolated human Schwann cells (hSCs) typically become senescent and unresponsive to mitogenic factors with continued in vitro expansion. Data from our lab has shown that adult nerve-derived hSCs, in contrast to rodent (rat) SCs, inevitably stop proliferating and acquire a senescent phenotype characterized by high levels of senescence-associated (SA)-β galactosidase activity and morphological changes that include cell enlargement and appearance of multi-nucleated cells. As opposed to rodent SCs, hSC cultures consist of mixed populations of proliferating cells, senescent cells and cells at different stages of differentiation regardless of the nerve of origin and other donor-specific factors. RNA-seq analysis of representative cultures of hSCs did not reveal the presence of telomerase reverse transcriptase (TERT) mRNA while other TERT-related genes (e.g. TERF1, telomeric repeat binding factor, and TEP1, telomerase-associated protein) were well-represented in the hSC transcriptome. In an attempt to overcome senescence, we used retroviral vectors and antibiotic selection to generate hSC lines ectopically expressing human (h)-TERT. For these experiments, highly proliferative, non-senescent, early passage hSC cultures were stably transduced with the retroviruses h-TERT-hygro or h-TERT-puro, each encoding the h-TERT gene along with hygromycin or puromycin resistance genes, respectively. Transduced hSC cultures from three different donors were selected and subjected to three rounds of expansion in medium containing chemical mitogens. Subsequently, the cultures were analyzed for their rate of proliferation by means of EdU incorporation assays and the acquisition of senescence by means of SA-β galactosidase activity assays in each round. We

found that whereas ectopic h-TERT expression extended the lifespan of cultured hSCs when compared to non-infected or GFP-expressing cells, it was not sufficient to confer immortalization and overcome senescence. In sum, our results suggest that progression of the hSCs to a senescent state likely is stress-induced rather than dependent on replication-associated telomere shortening.

Title: Role of neural stem factor sox2 in postnatal oligodendrocyte development

Authors: ***S. ZHANG**[1,2], C. CREATO[1], E. HAMMOND[1], D. PLEASURE[1,2], J. XU[1], L. SONG[1,2], F. GUO[1,2];

Abstract: Sox2, a SoxB1 transcription factor, plays an important role in maintaining the stemness of neural stem cells (NSCs) in both embryonic and adult ages in the central nervous system (CNS). It is generally thought that Sox2 is downregulatedor absent in the progenies derived from NSCs. Our previous study reports that Sox2 expression is maintained in the adult quiescent astrocytes (Guo et al., 2011 J Neurosci). Here, we showed a dynamic expression pattern of Sox2 in the oligodendroglial lineage cells.Sox2 is expressed at low level in virtually all oligodendroglial progenitor cells (OPCs) at both early postnatal and adult CNS, significantly upregulated in premyelinating oligodendrocytes (OLs) and downregulated in postmyelinating OLs after the completion of CNS myelination. Based on these observation, we hypothesize that Sox2 may play stage-dependent roles (**CNS developmental stages and oligodendrocyte developmental stages**) during postnatal oligodendrocyte development. Using inducible Cre-LoxP conditional knockout (cKO) system to ablate Sox2 in early postnatal OPCs, we

demonstrate Sox2 is required for OPC proliferation and dispensable for maintaining OPC survival in vivo during postnatal CNS development. The proliferation of OPCs (evidenced by Ki67 and EdU labeling) was significantly reduced in Sox2 cKO CNS compared to that in Sox2 wild type (WT) CNS whereas OPC apoptosis (evidenced by active caspase 3 and TUNEL labeling) was unaffected. Consistent with a reduction of OPC density, we demonstrated that the density of CC1+ differentiated OLs, including TCF7l2+ premyelinating OLs (Hammond et al., 2015, J Neurosci) was significantly decreased in Sox2 cKO CNS. Previous study has reported that Sox2 is dispensable for the proliferation of embryonic OPCs (Hoffman et al., 2014, Development). Our study suggests that Sox2 function in oligodendroglial lineage cells in a developmental stage-dependent (**embryonic versus postnatal**) manner. We are currently using genetic cKO system to specifically ablate Sox2 in oligodendroglial lineage cells downstream of OPCs and to determine the developmental stage-dependent role (**OPCs versus OLs**) along the linage progression of oligodendrocytes. Our study is likely to reveal a novel role of neural stem factor Sox2 in the development of oligodendroglial lineage cells.

Title: Regulation of oligodendrocyte differentiation by the control of B-cell CLL lymphoma 11B expression

Authors: C.-Y. WANG[1], K.-M. FANG[2], C.-H. HO[2], *S.-F. TZENG[3];
[1]Life Sci., [2]Natl. Cheng Kung Univ., Tainan, Taiwan; [3]Natl. Cheng Kung Univ., Tainan City, Taiwan

Abstract: B-cell CLL/lymphoma 11B (Bcl11b), known as CTIP2, is a C2H2 zinc finger transcriptional factor. It functions as a haploinsufficient tumor suppressor in T cells, and involves in DNA damage and cell apoptosis. Our previous study has indicated that the enriched

expression of Bcl11b was detected in tumorigenic C6 glioma cells. In the present study, we found that Bcl11b was highly expressed in glial progenitors (GPCs). The biological roles in GPCs and glioma cells were further determined by lentivirus-mediated knockdown (KD) approach. The results showed that inhibition of Bcl11b expression in GPCs not only halted their proliferation, but also reduced stemness-related gene expression in the growth condition. However, the expression of Notch signaling genes was not affected by Bcl11b KD. When maintained in the differentiation medium for 5 days, GPCs with Bcl11b KD differentiated into mature CNPase^{+} oligodendrocytes compared to those observed in mock culture. Moreover, through the co-culture of GPCs with hippocampal neurons, the processes of oligodendrocytes derived from Bcl11b-KD GPCs were highly co-localized with hippocampal fibers when compared to the control group. In addition, the in vivo study using lysolecithin-induced demyelinating animal model indicated that Bcl11b-KD GPCs injected to the lesioned site of the white matter gave rise to more MBP^{+}-oligodendrocytes than the control group had. Altogether, our results demonstrate that Bcl11b is generally required to maintain the cell proliferation of glial progenitors; however, the downregulation of Bcl11b expression might accelerate oligodendrocytic maturation.

Title: Zeb2 recruits Hdac-NuRD to inhibit Notch and controls Schwann cell differentiation and remyelination

Authors: *L. WU[1], J. WANG[1], J. R. CHAN[2], M. JANKOWSKI[1], D. HUYLEBROECK[3], Q. LU, 45229[1];
[1]CCHMC, Cincinnati, OH; [2]UCSF, San Francisco, CA; [3]KU Leuven Dept. of Develop. & Regeneration, Leuven, Belgium

Abstract: The mechanisms that coordinate and balance a complex network of opposing regulators to control Schwann cell (SC) differentiation remain elusive. Here we demonstrate that zinc-finger E-box binding-homeobox 2 (Zeb2/Sip1) transcription factor is a critical intrinsic timer that controls the onset of Schwann cell (SC) differentiation by recruiting HDAC1/2-NuRD co-repressor complexes. *Zeb2* deletion arrests SCs at an undifferentiated state during peripheral nerve development and inhibits remyelination after injury. Zeb2 antagonizes inhibitory effectors including Notch and Sox2. Importantly, genome-wide transcriptome analysis reveals a Zeb2 target gene, encoding the Notch effector Hey2, as a potent inhibitor for SC differentiation. Strikingly, a genetic Zeb2 variant, which is associated with Mowat-Wilson syndrome, disrupts the interaction with HDAC1/2-NuRD and abolishes Zeb2 activity for SC differentiation. Therefore, Zeb2 controls SC maturation by recruiting HDAC1/2-NuRD complexes and inhibiting a novel Notch-Hey2 signaling axis, pointing to the critical role of HDAC1/2-NuRD activity in peripheral neuropathies caused by *ZEB2* mutations.

Title: Ionotropic glutamate receptor-triggered cell signaling in Schwann cells

Authors: *W. M. CAMPANA[1,3], K. W. HENRY[1], E. MANTUANO[2,4], S. GONIAS[2];
[1]Anesthesiol., [2]Pathology, Univ. of California San Diego, La Jolla, CA; [3]Program in Neurosci., UCSD, La Jolla, CA; [4]Exptl. Medcine, Sapienz Univ. of Rome, Rome, Italy

Abstract: We previously demonstrated that rat Schwann cells (SCs) express the N-methyl-D-aspartate receptor (NMDA-R). In this study, we performed PCR to identify specific subunits of

ionotropic glutamate receptors in cultured rat SCs. The NMDA-R-associated subunits: NR1, NR2B, NR2C, NR2D, and NR3B were present at readily detected levels in SCs. We also detected the AMPA Receptor subunits: GluA1, GluA2, and GluA3, and the Kainate Receptor subunits: GluK2, GluK3, GluK4, and GluK5. To test whether SC ionotropic glutamate receptors trigger cell-signaling, cells were exposed to glutamate for 15 min. Protein phosphorylation was assessed using the R&D Systems Phospho-protein Proteome Profiler. Substantial phosphorylation events were noted, including ERK1/2 and c-Jun. The PI3K-Akt pathway was prominently activated, including the downstream kinase, p70 S6 kinase. Activation of Akt may have been supported by mTORC2. The transcription factor, CREB was phosphorylated as well. Proteome Profiler experiments were performed using human SCs and a strikingly similar signaling response to glutamate was noted.
Glutamate did not induce SC death at concentrations up to 1.0 mM. In Transwell cell migration experiments, glutamate significantly promoted SC migration ($p<0.05$). The effects of glutamate on SC migration were enhanced by adding glycine (50 nM). To determine which ionotropic glutamate receptor is responsible for the activity of glutamate in SC signaling, we studied ERK1/2 phosphorylation, as a representative cell-signaling event, by immunoblot analysis. ERK1/2 phosphorylation was substantially inhibited, by more than 50%, by MK801 or by silencing expression of the NR1 subunit of the NMDA-R. MK801 also inhibited SC migration induced by glutamate. Collectively, these results suggest that the NMDA-R plays a prominent role in eliciting SC responses to glutamate and may participate in SC trans-differentiation that is essential for nerve repair.

Title: Impact of Mtmr2 knockdown in Schwann cells

Authors: J. KIM, R. DOBROWOLSKI, *H. A. KIM;
Biol. Sci., Rutgers Univ. Newark, Newark, NJ

Abstract: Charcot-Marie-Tooth 4B1 is a form of inherited peripheral neuropathy that affect myelin in the peripheral nervous system (PNS). In human, the mutations affect the gene for

myotubularin-related protein 2 (Mtmr2) in an autosomal recessive manner. Genetic knockdown of Mtmr2 in mice recapitulates several aspects of CMT4B1, including reduced nerve conduction, loss of myelinated axons and myelin out-folding. More important, a previous study has shown that loss of Mtmr2 in Schwann cells, not neurons, contributes to the PNS myelin abnormalities, indicating the importance of the Schwann cell intrinsic function of Mtmr2 in normal development of the PNS myelin.
Mtmr2 is a phosphoinositide 3-phosphatase that uses PI(3,5)P2 and PI(3)P to generate PI(5)P and PI, respectively. A previous study has shown that Mtmr2 loss results in accumulation of PI(3,5)P2 in cells, indicating that the Mtmr2-associated myelin abnormalities may be due to dysregulation of the biological function related to PI(3,5)P2. PI(3,5)P2 is found within the endomembrane system, specifically within membranes of late endosomes and lysosomes. Therefore, it is possible that aberrant regulation of the endo-lysosome system may contribute to the myelin dysregulation in Schwann cells.
To investigate the effects of Mtmr2 loss in Schwann cells, we used lentivirus-mediated shRNA transduction to generate Schwann cell cultures in which Mtrm2 protein levels were knocked-down (KD) by 70-80%. While the morphology of Mtmr2 KD Schwann cells was indistinguishable from control cells under non-differentiation condition, upon differentiation by cAMP, the KD Schwann cells exhibited expanded membrane protrusions and enlarged cell bodies. A similar change in cell morphology was also evident when the Schwann cells were placed in contact with DRG neurons. Western blot analysis on differentiated KD Schwann cells showed a marked decrease in Krox 20, a pro-myelinating transcription factor, but no difference in myelin protein expression compared to the control cells. In the KD cells, we also observed an increase in the inhibition (phosphorylation) of Ulk1, a kinase that promotes autophagosome biogenesis. Mtmr2 KD Schwann cells expressed lower levels of p62 compared to the control, which may indicate a defect in autophagosome formation. Interestingly, autophagic flux appears to occur normally in the KD cells, indicating the presence of functional lysosomes. Altogether, our data show that loss of Mtmr2 in Schwann cells impacts cell morphology, Schwann cell differentiation and autophagy.

Title: Schwann cell population responses to nerve stimulation

Authors: *T. W. GOULD, D. J. HEREDIA, G. W. HENNIG;
Physiol. and Cell Biol., Univ. of Nevada Sch. of Med., Reno, NV

Abstract: Terminal/perisynaptic Schwann cells at the adult neuromuscular junction (NMJ) respond to and regulate neurotransmission. During the early postnatal period of developmental synapse elimination, Schwann cells differentially decode competing neural inputs and help drive the turnover of these inputs by competing with them for space on the postsynaptic muscle fiber. During the embryonic period of synapse formation, Schwann cells maintain nascent synapses by antagonizing the effects of neural activity. Therefore, we have been characterizing the effects of peripheral motor nerve stimulation on Schwann cell calcium responses at the mouse neonatal neuromuscular junction (NMJ) using genetically encoded calcium indicators. We found that in the postnatal day 0 (P0) diaphragm muscle, phrenic nerve stimulation at a frequency and duration that causes a rundown of neurotransmitter release resulted in a robust accumulation of calcium by Schwann cells in the diaphragm. Interestingly, low-frequency nerve stimulation also induced calcium responses in Schwann cells at P0. The intensity, rise-to-peak intensity, duration, onset, and temporal heterogeneity of these Schwann cell calcium responses varied according to stimulation frequency and duration. We also examined the spatial pattern of Schwann cell responses to nerve stimulation over time. Whereas all Schwann cells at the NMJ and along pre-terminal axon branches responded to nerve stimulation at P0, only those at the NMJ responded at P7 and older. In contrast, Schwann cells along major phrenic nerve branches, as well as some but not all Schwann cells along terminal branches and at nascent NMJs, responded to nerve stimulation at early embryonic ages (E14-E15). Consistent with a previous report, the calcium accumulation within all Schwann cells during the neonatal period was completely blocked by a specific antagonist to P2YR1 receptors. These studies suggest that Schwann cells respond differentially to nerve stimulation at early ages. Further work is required to understand the mechanism underlying these differential responses.

Abstract: Canavans Disease (CD) is a fatal autosomal-recessive leukodystrophy primarily affecting children under one year of age. It is caused by mutations in the aspartoacylase gene (ASPA). The enzyme encoded by this gene cleaves N-acetylaspartate (NAA), yielding aspartate and acetate. The pathology is characterized by massive vacuolization of the brain and loss of myelin. The pathogenetic mechanisms underlying these phenotypes remain elusive. Here we employ human induced pluripotent stem cells (iPSCs) derived from four CD patients to model aspects of this disease in cell culture. Specifically, we reprogrammed patient fibroblasts using Sendai viral vectors encoding Sox2, Oct3/4, Klf4 and c-Myc. Resulting CD-hiPSCs were fully validated for virus inactivation, pluripotency marker expression (Tra1-60, Tra1-81, SSEA4) and their ability to differentiate into all three germ layers *in vitro* and *in vivo*. CD-hiPSCs were then differentiated into stably self-renewing radial glia-like neural progenitor cells (RGL-NPCs) according to a recently established protocol (Gorris et al., Glia 63:2152-67, 2015). These RGL-NPCs express typical radial glia markers including BLBP, CD133, Nestin, Sox2, Sox9 and Pax6 and were used to generate CD-specific βIII-tubulin-/MAP2-positive neurons, O4-/MBP-positive oligodendrocytes and GFAP-positive astrocytes for phenotypic analysis. Detailed immunofluorescence and electron microscopic analyses revealed that CD-specific astrocytes contain significantly larger mitochondria with abnormally structured cristae. Specifically, Feret's diameters of mitochondria in CD-specific astrocytes were enlarged to 1.26 ± 0.06 μm (controls from healthy donors: 0.83 ± 0.05 μm; $p<0.005$). These observations correspond well with previous reports on mitochondrial aberrations in astrocytes of CD autopsy specimens, indicating that this pathological hallmark can be modeled in an in vitro iPSC system. We expect this model to provide further information on disease-specific metabolic alterations, potential pathological changes in neurons and oligodendrocytes, and the role of cell-autonomous and non cell-autonomous pathomechanisms underlying this disease.

Title: Efficient pharmacogenetic ablation of oligodendrocyte progenitor cells (NG2 glia) in mice

Authors: *T. D. MERSON[1,2], B. H. A. CHUANG[2], T. J. KILPATRICK[3], Y. L. XING[2]; [1]Florey Dept of Neurosci. and Mental Hlth., University Of Melbourne, Australia; [2]Florey Inst. of Neurosci. and Mental Hlth., Parkville, Australia; [3]Dept of Anat. and Neurosci., Univ. of Melbourne, Parkville, Australia

Abstract: Remyelination of the central nervous system is primarily achieved by generating new myelin-forming oligodendrocytes, which can be derived from both parenchymal oligodendrocyte progenitor cells (OPCs/NG2 glia) and neural precursor cells (NPCs) that reside in the adult subventricular zone (SVZ). Our previous studies have demonstrated that NPCs are major contributors to oligodendrogenesis and remyelination following cuprizone-induced demyelination, but on a regionally restricted basis. We demonstrated that NPC-derived oligodendrocytes predominantly remyelinate regions of the demyelinated corpus callosum that are adjacent to the SVZ whereas OPC-derived oligodendrocytes occupy regions of the remyelinated corpus callosum that are distal to the SVZ. To explore whether the regionally restricted migration of NPCs reflects spatial competition with OPCs for oligodendrogenesis and remyelination, an approach to conditionally ablate OPCs while sparing the NPC population is required. Here we describe a highly efficient methodology to conditionally ablate parenchymal OPCs by comprising both genetic and pharmacological techniques. This approach could be adopted to examine the influence of OPC ablation upon the regenerative capacity and function of NPC-derived oligodendrocytes in demyelinating disease. In addition, the model provides a long sought after methodology to investigate the function of OPCs/NG2 glia in the normal healthy brain.

Title: Regulatory function of nogo-a in oligodendrocyte differentiation

Authors: *M. A. MAIBACH, F. MÜLLER, O. WEINMANN, M. E. SCHWAB;
Health, Sci. and Technol., ETH Zürich, Zürich, Switzerland

Abstract: The membrane protein Nogo-A was discovered in 1988 as a myelin-associated inhibitor of neurite outgrowth and regeneration in the adult central nervous system (CNS). In the following decades, Nogo-A emerged as a regulator of various other developmental and plastic processes such as synapse formation and neuronal migration. While Nogo-A is expressed by subtypes of neurons early in development, Nogo-A is mainly expressed throughout the oligodendroglial lineage in the postnatal CNS. Nogo-A signals via two extracellular regions termed Nogo-66 and Nogo-A-Δ20. The Nogo-66 signals are transduced by a Nogo Receptor 1 (NgR1) containing receptor complex, while the Nogo-A-Δ20 receptor was unknown for a long time. Recently, we identified sphingosine 1-phosphate receptor 2 (S1PR2), a member of the G protein coupled receptor (GPCR) superfamily, as a receptor for the Nogo-A-Δ20 domain (Kempf et al., 2014). This is of particular interest because the function blocking anti-Nogo-A antibody 11C7, which enhances compensatory sprouting and functional recovery after CNS trauma, targets the Nogo-A-Δ20 domain.
While the immediate cascades of Nogo-A signalling leading to growth cone collapse and retraction are well established, little is known about the physiological role of Nogo-A in oligodendroglia. Nogo-A is expressed throughout the oligodendroglial lineage and the differentiation stage specific composition of the receptor complexes is currently under examination. We previously showed that systemic Nogo-A knock out mice exhibit a postnatal delay in myelination that normalizes after one month (Pernet et al., 2008). To investigate the cause of this transient hypomyelination, oligodendrocyte differentiation dynamics were analysed in postnatal Nogo-A knock out and wild type control mice by immunofluorescent stainings for stage specific markers. Preliminary results indicate that Nogo-A knock out animals show a delay in oligodendrocyte maturation. In contrast, no effect of Nogo-A on oligodendroglial survival was

found, indicating a specific role of Nogo-A in oligodendrocyte differentiation. Further research into the underlying mechanisms will be conducted to possibly find new ways of enhancing remyelination in myelin related diseases such as multiple sclerosis.

Title: MicroRNA control of myelination and remyelination in the CNS

Authors: ***H. WANG**, Z. MA, Y. DENG, R. LU;
Cincinnati Children's Hosp., Cincinnati, OH

Abstract: microRNAs (miRNAs) have been implicated in oligodendrogenesis and demyelinating diseases; however, underlying specific miRNAs have remained elusive. Through *in vivo* targeted mutagenesis in mice, we find that miR-219 is required for proper oligodendrocyte differentiation and myelination. Temporally-specific ablation reveals a critical role for miR-219 in oligodendrocyte remyelination after lysolecithin-induced demyelination, while miR-219 overexpression promotes precocious oligodendrocyte maturation and myelin regeneration. Accordingly, administration of miR-219 mimics to lysolecithin-induced demyelinating lesions in the murine spinal cord enhances myelin restoration. Through an integrated transcriptome profiling and biotin-affinity miRNA pull-down approach, we identify stage-specific targeting of differentiation inhibitors by miR-219, and further uncover novel sets of miR-219 targets including Etv5 and Lingo1 that inhibit oligodendrocyte maturation. Inhibiting *Etv5* and *Lingo1* leads to a partial rescue of differentiation defects in *miR-219*-deficient oligodendrocyte culture. Together, our findings identify context-specific miRNA-regulated checkpoints that control CNS myelinogenesis and myelin repair.

Title: Fyn-Dab1 signaling during oligodendrocyte differentiation

Authors: ***D. J. OSTERHOUT**, H. BHATTI, I. I. GENEVA;
Dept Cell & Developmental Biol, SUNY Upstate Med. Univ., Syracuse, NY

Abstract: Oligodendroglial progenitor cells (OPCs) are the precursors to myelinating oligodendrocytes in the central nervous system (CNS). These cells are generated in the ventral neuroepithelium at later stages of cortical development, migrating into the cortex where they contact axons and ultimately form a myelin membrane. During the process of differentiation, OPCs undergo significant morphological changes, extending many branched processes which will make contact with axons. Once in contact with an axon, the oligodendrocyte process expands and begins to form the myelin membrane which will ensheathe the axon.
The morphological differentiation of oligodendroglial progenitor cells, from a simple bipolar cell to a cell with multiple complex processes, is a key requirement for myelin formation. The activation of the tyrosine kinase Fyn is an early step in the differentiation of oligodendroglial progenitor cells. Fyn activation occurs in oligodendroglial progenitor cells even before any changes in cellular morphology are observed. Once active, Fyn regulates the morphological differentiation of these cells, initiating process outgrowth and myelin sheet formation *in vitro.* In Fyn deficient mice, myelin formation is markedly reduced, demonstrating the importance of this kinase in myelination *in vivo*.
Fyn interacts with many downstream effectors, including molecular signaling pathways that interact with the cytoskeleton and initiate process outgrowth.This includes the adaptor protein Dab1. Our early work has demonstrated that Fyn-Dab1 interactions are important for OPC migration, as animals deficient in either Fyn or Dab1 show reduced OPC migration from the subventricular zone *in vivo*. In the present study, we show that Fyn-Dab1 interactions with cytoskeletal components in the cell are important for the initiation of process outgrowth.

Title: Acute oligodendrocyte loss and persisting white matter injury in a third trimester equivalent model of fetal alcohol spectrum disorder

Authors: J. C. NEWVILLE[1], C. F. VALENZUELA[1], L. LI[1], L. L. JANTZIE[2], *L. A. CUNNINGHAM[1];
[1]Neurosciences, [2]Pediatrics, Univ. of New Mexico Sch. of Med., Albuquerque, NM

Abstract: Recent human imaging studies have linked white matter abnormalities in the corpus callosum with cognitive impairment in children with fetal alcohol spectrum disorder (FASD), however, the underlying mechanisms remain unknown. The Nestin-CreER^{T2}/tdTomato strain was used in the current study to evaluate the acute and persisting impacts of alcohol exposure on oligodendrocyte number and white matter integrity in a third-trimester equivalent mouse model of FASD. Nestin-CreER^{T2}/tdTomato pups received a single intraperitoneal injection of tamoxifen (33 mg/kg) at postnatal day 2 (P2) to label oligodendrocyte lineage cells derived from the postnatal subventricular zone (SVZ; Olig2^{+}/tdTomato^{+}), distinguishing them from those that originated during embryonic development (Olig2^{+}/tdTomato^{-}). Cages containing both mothers and pups were placed into inhalation chambers where they were exposed to ethanol vapor or air for four hours daily from P3 through P15, resulting in a mean pup blood ethanol concentration of 160.4 ± 12.0 mg/dl (range = 128.2 – 185.6 mg/dl). Stereological analysis in septal corpus callosum of tdTomato^{-} oligodendrocytes (OLs) demonstrated a 53% decrease in the number of mature OLs (CC1^{+}/Olig2^{+}; EtOH 20,162 ± 3,944 cells/mm^3, n=3; Air 42,804 ± 5,058 cells/mm^3, n=5; p=0.0125), and a 75% decrease in proliferating oligodendrocyte progenitor cells (OPCs; Ki67^{+}/Olig2^{+}; EtOH 1,608 ± 658.0 cells/mm^3, n=3; Air 6,276 ± 1,232 cells/mm^3, n=5; p=0.0169) at P16 following early postnatal ethanol exposure. By P50 both tdTomato^{-} mature OL and proliferating OPC numbers recovered compared to those of air controls. Interestingly, there was no effect of alcohol on the numbers of tdTomato^{+} OLs or OPCs cells at either P16 or P50, suggesting heterogeneity of oligodendrocyte alcohol susceptibility dependent on ontogenetic origin. Further characterization of white matter injury in the corpus callosum at P50 indicated persisting myelin protein dysregulation and microstructural abnormalities of alcohol-exposed subjects, as assessed by western immunoblotting of myelin basic protein (MBP; increased

expression) and MRI diffusion tensor imaging (DTI; decreased fractional anisotropy). These results demonstrate that third-trimester equivalent alcohol exposure leads to an acute, transient decrease in OL lineage cell numbers, accompanied by enduring white matter injury. Additionally, our finding of heterogeneity in alcohol susceptibility based on the developmental origin of OLs may have therapeutic implications in FASD and other disorders of white matter development.

Title: Heterogeneity of astrocyte and NG2 cell insertion at the node of Ranvier

Authors: ***P. JUKKOLA**, D. R. SERWANSKI, A. NISHIYAMA;
Physiol. and Neurobio., Univ. of Connecticut, Storrs, CT

Abstract: The node of Ranvier is a functionally important site on the myelinated axon where sodium channels are clustered at a high density, allowing rapid saltatory conduction of action potentials. Early ultrastructural studies have revealed the presence of “glia” or “astrocytes” at the nodes. NG2 cells, also known as oligodendrocyte precursor cells or polydendrocytes, comprise a population of resident glial cells in the mature mammalian central nervous system that is distinct from astrocytes, and processes of NG2 cells have been detected at the nodes. However, the frequency of the occurrence of the two types of glia at the node has remained unknown. We have used specific cell surface markers to examine the prevalence of NG2 cells and astrocytes at the node of Ranvier in the optic nerve, corpus callosum, and spinal cord of young adult mice or rats. We show that >96% of the nodes in all three areas contained astrocyte processes, while 33-49% of nodes contained processes from NG2 cells. Only a few nodes appeared devoid of glial apposition. Intriguingly, NG2 cell processes showed a clear preference for larger nodes of

Ranvier. The heterogeneity of glial processes at the nodes was confirmed by stimulated emission depletion (STED) confocal microscopy and by electron microscopy. Electron microscopy using unlabeled and pre-embedding immunolabeled tissue revealed differences in the spatial relationship of each type of glia to the nodal structure. These findings provide a morphological basis for future investigations on the role of NG2 cells and astrocytes in nodal function and white matter plasticity.

Title: Glycogen synthase kinase 3 β inhibition promotes myelination in preterm rabbit pups with intraventricular hemorrhage

Authors: *P. DOHARE, F. HU, P. BALLABH;
Pediatrics, Cell biology and Anat., New York Med. Col., Valhalla, NY

Abstract: Intraventricular hemorrhage (IVH) in preterm infants results in white matter injury and neurological deficits. Reduced myelination in infants with IVH is attributed to reduced proliferation and arrested maturation of oligodendrocyte progenitor cells (OPCs). Glycogen synthase kinase 3 β (Gsk-3β) proteins regulate proliferation and maturation of neural cells during development. Studies have shown that Gsk-3β inhibition enhances proliferation and differentiation of OPCs and myelination of the white matter in neonatal rats as well as in adult models of demyelination. Therefore, we hypothesized that Gsk-3β inhibition might promote multiplication and maturation of OPCs, and accelerate myelination in rabbit pups with IVH. To test our hypotheses, we employed preterm rabbit (E29, Term=32d) model of glycerol-induced IVH. We treated pups with IVH by ARA-014418 (ARA, 20 mg/kg twice a day), a Gsk-3β inhibitor, or vehicle for 7 days, and compared the expression of myelin basic protein (MBP), myelin associated glycoprotein (MAG), and GFAP between ARA- and vehicle-treated pups with IVH at postnatal day (D) 14 using immunohistochemistry and Western blot analyses. We found that ARA treatment increased phospho-Gsk-3β levels (serine9), however did not affect activate β-catenin or TCF4 levels at D3 in preterm pups with IVH, suggesting failure of ARA to

upregulate Wnt signaling in pups with IVH despite evidence of its activity. More importantly, we noted that MBP and MAG levels were elevated in ARA treated pups with IVH compared to vehicle controls at D 14 on both immunohistochemistry and Western blot analyses ($P<0.05$, all comparisons). ARA treatment did not affect GFAP expression in pups with IVH. NICD (Notch intracellular domain) levels were significantly reduced in ARA treated pups relative to controls ($P<0.05$) and Hes5 levels showed a trend toward decrease in ARA treated pups. Additionally, ARA treatment increased Sox2 and reduced Dlx1 levels in pups with IVH. Data suggest that Gsk-3β inhibition by ARA treatment promotes myelination in rabbit pups with IVH. Notch inhibition, an increase in neural progenitor pool, and a shift in the fate of multipotent progenitors from interneuron precursors to OPCs might be contributing to enhanced myelination in rabbits with IVH. We speculate that ARA treatment might promote myelination and neurological recovery in human premature infants with IVH.

Title: Association between stress-induced Ranvier nodes structural abnormalities and reduced oligodendrocyte activity in major depressive disorder

Authors: *S. MIYATA, S. SHIMIZU, T. TANAKA, M. TOHYAMA;
Kindai Univ/ Res. Ins Trad Asian Med., Osaka-Sayama, Osaka, Japan

Abstract: Major depressive disorder is probably the oldest and still one of the most frequently diagnosed psychiatric illnesses. Major depressive disorder is one of the leading causes of disturbances in emotional, cognitive, autonomic, and endocrine functions, affecting nearly 7% of the population in Japan. According to the large amount of information on depressive diseases that has been accumulated during recent years, patients with major depressive disorder show an enhanced biologic stress-response mechanism, especially a hyperactive hypothalamic-pituitary-adrenal (HPA) axis and high levels of circulating cortisol. Although dysregulation of the HPA axis by chronic stress is indicative of major depressive disorder, the molecular mechanisms and functional changes in the brain underlying depression are largely unknown. In this study, we have developed an animal model of depression by exposing mice to chronic stress. These mice show depression-like symptoms including chronically elevated plasma levels of corticosterone. We previously showed oligodendrocyte (OL)-specific activation of the serum/glucocorticoid-regulated kinase (SGK)1 cascade, increased expression of axon-myelin adhesion molecules, and elaboration of the oligodendrocytic arbor in the corpus callosum of chronically stressed mice. In the current study, we demonstrate that the nodes and paranodes of Ranvier in the corpus callosum were narrower in these mice. Chronic stress also led to diffuse redistribution of Caspr and Kv 1.1 and decreased the activity in white matter, suggesting a link between morphological changes in OLs and inhibition of axonal activity. OL primary cultures subjected to chronic stress resulted in SGK1 activation and translocation to the nucleus, where it inhibited the transcription of metabotropic glutamate receptors (mGluRs). Furthermore, the cAMP level and membrane potential of OLs were reduced by chronic stress exposure. We showed by diffusion tensor imaging that the corpus callosum of patients with MDD exhibited reduced fractional anisotropy, reflecting compromised white matter integrity possibly caused by axonal damage. Our findings suggest that chronic stress disrupts the organization of the nodes of Ranvier by suppressing mGluR activation in OLs, and that specific white matter abnormalities are closely associated with MDD onset.

Title: Protease activated receptor 2 is a novel regulator of myelin development and repair.

Authors: *I. A. SCARISBRICK[1], M. RADULOVIC[2], H. YOON[2];
[2]Physical Med. and Rehabil., [1]Mayo Clin., Rochester, MN

Abstract: Oligodendrocytes are essential regulators of nerve impulse conduction and energy homeostasis in the developing and adult central nervous system and therefore represent an important target for the design of therapies to promote recovery of function in cases of injury and disease. In this study, we evaluated the role of a unique protease activated G-protein coupled receptor referred to as protease activated receptor 2 (PAR2) in spinal cord myelin development and repair. PAR2 is a seven transmembrane G-protein-coupled receptor that becomes activated upon enzymatic cleavage within its extracellular domain. PAR2 is therefore positioned to serve as a key translator of the proteolytic microenvironment into cellular responses that regulate myelin homeostasis and regeneration. A systematic comparison of patterns of myelination in the spinal cord of wild type and PAR2 knockout mice revealed that those with PAR2 loss-of-function exhibited earlier onset of myelin production and overall acceleration of myelination during the postnatal period and into adulthood. The pro-myelinating effects of PAR2-loss-of-function included higher proteolipid protein (PLP) levels at birth, more Olig2+ oligodendrocytes at P7, and more mature CC1+ myelinating cells by P7 and P21. Moreover, the spinal cord of mice lacking PAR2 displayed overall higher levels of myelin basic protein (MBP) and thickened myelin sheaths in adulthood compared to mice with an intact PAR2 signaling system. Enhancements in myelination with PAR2 loss-of-function were accompanied by increases in the pro-myelination signaling pathway pERK1/2 within the spinal cord from P7 onwards. Supporting a direct role for PAR2 as a suppressor of myelination, oligodendrocyte progenitor cells (OPCs) derived from PAR2-null mice, or wild type OPCs treated with a PAR2 small molecule inhibitor, expressed higher levels of the major myelin proteins PLP and MBP. PAR2 loss-of-function also improved the preservation of myelin in the context of traumatic spinal cord injury. Collectively, these studies point to signaling at PAR2 as a novel suppressor spinal cord myelination during postnatal development and as a critical regulator of myelin integrity after injury of the adult spinal cord. Therefore, PAR2 represents a new target for therapies aimed at promoting myelination developmentally and myelin preservation in neurological disorders such as spinal cord injury where white matter injury is a central concern.

Title: Motor neuron sonic hedgehog regulates oligodendrocyte proliferation and maturation in the developing spinal cord

Authors: *L. STARIKOV[1,2], A. KOTTMANN[1,2];
[1]Physiology, Pharmacol. and Neurosci., Sophie Davis Sch. of Biomed. Education, CUNY, New York, NY; [2]Molecular, Cellular, and Developmental Biol., CUNY Grad. Ctr., New York, NY

Abstract: Sonic hedgehog (Shh) secreted from transient organizing tissues such as notochord and floorplate during development determines neuronal and glial cell fate and exemplifies the classic principle of a morphogen. We find that besides the floorplate, post mitotic motor neurons (MNs) are an additional ventral source of Shh important for regulating the specification and maturation of oligodendrocyte precursors (OPCs) originating from the Olig2 domain during spinal cord development. Consistent with the anterior to posterior birth wave of oligodendrocytes in the spinal cord, we find a delay in the generation and migration of OPCs in Olig2cre; $Shh^{L/L}$ mutant animals that have Shh ablated from selectively MNs in an anterior to posterior pattern. Although OPC numbers and density seem to recover by E16.5 in mutant animals, OPC morphology in mutants is affected into postnatal life, leaving open the possibility of motor neuron Shh dependent lasting epigenetic regulation of OPCs during a critical window of OPC generation from the Olig2 domain.

Abstract: The reticulons (RTNs) are a family of transmembrane proteins found in the endoplasmic reticulum (ER) as well as in smaller though functionally relevant quantities at the plasma membrane. They all share a common C-terminal transmembrane reticulon homology domain (RHD); however, the N-termini of RTNs differ greatly with respect to length, structure and function. The most studied member of this family, Nogo-A (RTN4A), has an almost 1000 amino acid long N-terminus important for the signaling function of the protein as an inhibitor of neurite outgrowth and a regulator of synaptic plasticity in the central nervous system (CNS). Nogo-B (RTN4B), a splice variant of Nogo-A, has a much shorter N-terminus of approximately 170 amino acids which it shares with the very N-terminus of Nogo-A. The function of Nogo-B is nonetheless much less clear though it has been described as a regulator of apoptosis and vascular remodeling.
The current view of Nogo signaling is that plasma membrane-bound full-length Nogo initiates signaling cascades through binding to receptors on cells in direct contact with the Nogo expressing cell. However, the presence of Nogo sequences in bodily fluids such as the cerebrospinal fluid (CSF) has been anecdotally reported and recently found in a proteomic study (Chiasserini *et al.*, 2014). As the presence of functionally active Nogo in the CSF and other bodily fluids would have major implications e.g. for the *in vivo* administration of anti-Nogo-A antibodies as therapies, we sought to investigate whether either full-length or cleaved fragments of Nogo are released into the supernatant of cultured neuron-like cells. We found that full-length Nogo-A, full-length Nogo-B, as well as cleaved fragments which include the shared N-terminus of Nogo-A/-B, are found in the culture supernatant of N2a neuroblastoma cells. Both the full-length proteins as well as the cleaved fragments were associated with extracellular vesicles rather than free in solution. Furthermore, we found that extracellular vesicles from the cerebrospinal fluid (CSF) of adult rats are enriched in full-length Nogo-A, but not Nogo-B or the N-terminal cleaved fragments. Current work is focused on assessing the functionality of vesicle-bound Nogo-A as a ligand, and evaluating the significance of the proteolytic processing of Nogo-A/B in the context of Nogo signaling.

Title: Sox17 suppression of Wnt/beta-catenin promotes oligodendrocyte regeneration through Hedgehog-Smoothened signaling

Authors: *L.-J. CHEW, X. MING, B. MCELLIN, V. GALLO;
Ctr. Neurosci Res., Children's Res. Inst., Washington, DC

Abstract: Sox17 is the only Sox F transcription factor to be analyzed in the brain, and it has been shown to promote oligodendrocyte (OL) development. Sox17 is expressed in regenerating OLs of adult white matter (WM) lesions, but its role in repair is not understood. Sox17 overexpression in CNPSox17 transgenic mice was found to promote postnatal OL development and prevent OL loss after focal lysolecithin (Lyso) demyelination. Our present studies show that CNPCre-mediated Sox17 ablation (cko) results in a transient developmental decrease in postnatal Olig2+ OL lineage cells at P30, which is followed by recovery. WM recovery after Lyso demyelination is delayed in the cko as lesions fail to regain MBP expression at 14DPL, accompanied by reduced nascent MAG+ cells. Since Sox17 inhibits Wnt/beta-catenin signaling in vitro, its ablation in vivo may elevate beta-catenin activity. Increased unphosphorylated beta-catenin (active, ABC) levels were found in the cko, which were further increased after Lyso. Conversely, demyelination-induced ABC was not observed in CNPSox17 lesions. Fewer ABC+Iba1+ microglia and ABC+Caspase3+ cells indicated attenuated damage and reactivity. OL regeneration was increased, evidenced by increased BrdU+Olig2+ cells. Reduced b-catenin activation may promote progenitor maturation to OLs, which were increased in CNPSox17 lesions. Stereotaxic injection of the b-catenin antagonist CCT036477 into C57Bl6 mouse lesions not only improved OL generation, but also prevented Caspase3+ cell increase. Although total beta-catenin was increased in intact CNPSox17 WM, ABC levels did not increase proportionately, suggesting tonic repression by Sox17. Surprisingly, Sox17 was not detected in b-catenin immunoprecipitates from adult CNPSox17 WM, so that b-catenin inhibition may be indirect. Since GLI2 was previously found to be elevated in CNPSox17, Hedgehog signaling is a possible candidate. PDGFR-Cre-mediated ablation of *Gli2* or Smoothened (*Smo*) at P60 increased ABC+ cells in intact WM, indicating Hedgehog repression of Wnt/b-catenin. Pharmacological GLI inhibition renders the CNPSox17 WM vulnerable to Lyso damage.

Stereotaxic application of the SMO agonist SAG in C57Bl6 Lyso lesions, similarly to CNPSox17, prevented the ABC increase and promoted OPC differentiation, supporting Hedgehog-mediated OL regeneration. This is consistent with enhanced Smo activation in CNPSox17 lesions, and *Smo* ablation in CNPSox17 lesions results in a large increase in ABC at 3DPL. These studies in Sox17 mutant strains thus reveal a negative regulatory relationship between Hedgehog and Wnt/b-catenin that is integrated and enhanced by Sox17 during OL regeneration.

Title: Pain-induced spinal NG2 cell proliferation: a critical role of β-catenin in neurons but not in NG2 cells

Authors: *Y. SHI, S.-J. TANG;
Neurosci. and Cell Biol., Univ. of Texas Med. Br., Galveston, TX

Abstract: NG2 neural stem cells are oligodendrocyte precursors that critically contribute to myelination during development and/or remyelination in response to central nervous system (CNS) injuries. Emerging evidence suggests that neuronal activity intimately regulates the proliferation of NG2 cells, probably via the neuron-NG2 synapses. We hypothesize that NG2 cells in the pain neural pathway respond to nociceptive stimulation and potentially regulate pain pathogenesis. To test this hypothesis, we injected capsaicin (i.d.) in the mouse hind paw and quantified NG2+ cells in the spinal dorsal horn (SDH). We observed a significant increase of NG2+ cells in the superficial layers of the SDH in the capsaicin-treated group. About 70% of NG2+ cells were also Olig2-positive, indicating that they were progenitors of oligodendrocytes. Bromodeoxyuridine (BrdU) labeling experiments indicated that capsaicin-induced NG2+ cell increase was resulted from cell proliferation. To understand the mechanism by which pain signals stimulate NG2 cell proliferation, we tested the role of β-catenin, because recent studies

suggest its important role in regulating NG2 cell proliferation and differentiation during development or remyelination. Intrathecal injection (i.t.) of β-catenin inhibitor XAV939 blocked capsaicin-induced NG2+ cell increase. To specifically determine the role of β-catenin, we generated conditional knockout (CKO) mice. Surprisingly, deletion of β-catenin in NG2 cells did not attenuate capsaicin-induced NG2+ cell increase. In contrast, deletion of one copy of β-catenin in neurons blocked the increase of NG2+ cells. These unexpected findings suggest that β-catenin in neuron might be critical for generating a neuron-to-NG2 signal that elicits NG2 cell proliferation in response to painful stimulation.

Abstract: Exposure to valproic acid (VPA) during pregnancy has been linked with increased incidence of autism, and has repeatedly been demonstrated as a useful autism mouse model. We examined the early behavioral and anatomical changes as well as molecular changes in mice prenatally exposed to VPA (VPA mice). In this study, we first showed that VPA mice showed developmental delays as assessed with self-righting, eye opening tests and impaired social recognition. In addition, we provide the first evidence that primary cultured neurons from VPA-treated embryos present an increase in dendritic spines, compared with those from control mice. Mutations in phosphatase and tensin homolog (PTEN) gene are also known to be associated with autism, and mice with PTEN knockout show autistic characteristics. Protein expression of PTEN was decreased and the ratio of p-AKT/AKT was increased in the cerebral cortex and the

hippocampus, and a distinctive anatomical change in the CA1 region of the hippocampus was observed. Taken together, our study suggests that prenatal exposure to VPA induces developmental delays and neuroanatomical changes via the reduction of PTEN level and these changes were detectable in the early days of life.

Abstract: Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by deficits in social communication and a pattern of repetitive stereotyped behaviors. Many studies have been reported that high rates of mental health problems are observed commonly in ASD, especially depression and anxiety. Therefore, early detection is important to intervene early and prevent later psychiatric symptoms. Despite all the research efforts, however, reliable diagnostic biomarkers are not established as it stands. MicroRNAs (miRNAs) are a class of short non-coding RNAs that regulate gene expression. Increasing evidence has shown that miRNAs may play essential roles in neurodevelopmental disorders.
In this study, we evaluated blood-based microRNAs as novel biomarkers for diagnosis of ASD. We determined miRNA expression profiles of ASD using Agilent miRNA microarray analysis in discovery sample set (30 ASD patients and 30 Controls). An independent replication sample set was used for the biomarker validation by real-time RT-PCR. Further we constructed ROC (Receiver Operating Characteristics) curves to determine the sensitivity and specificity of individual miRNA as a diagnostic biomarker. We found that three miRNAs had significantly altered in ASD patients compared to healthy controls and also got a good ROC curve according

to the accepted classification of biomarker utility. These miRNAs were expressed in not only blood but also human brain. Our findings provide novel and reliable biomarkers for diagnosis of ASD.

Title: Autism-related protein MeCP2 regulates FGF13 expression and emotional behaviours

Authors: *B. YUAN;
Inst. of Neurosci., Shanghai City, China

Abstract: Background
MeCP2 protein functions through either repressing gene expression transcriptionally by recruiting HDAC complexes or post-transcriptionally suppressing nuclear microRNA processing. Mutations and copy number variations of the MECP2 gene are associated with Rett syndrome and autism spectrum disorders. FGF13 is a microtubule binding protein and plays a critical role in regulating neural development. Loss of the FGF13 gene leads to severe intellectual disabilities in human.
Results
Here we found that MeCP2 regulates the expression of FGF13 via two distinct microRNAs. The protein level of FGF13 decreased in Mecp2 knockout mice and elevated in MeCP2 overexpression mice, indicating the regulatory cascade of MeCP2 to FGF13. Importantly, we found that abnormal elevated fear conditioning behaviors in MeCP2 overexpression mice overcome the defective fear learning behaviors of FGF13 knockout mice, suggesting the molecular axis of regulating fear learning and memory by the MeCP2-FGF13 regulatory cascade. However, the anxiety behaviors of MeCP2 overexpression and FGF13 knockout mice seem not to compensate with each other.
Conclusions

This work provides a functional connection between two critical disorder-related genes, MeCP2 and FGF13, further suggesting that behavioral abnormalities found in mouse models of brain disorders may be compensated with each other, if genetic causes are within the same regulatory axis.

Title: Shank2 and Shank3 gene - environment interactions in autism spectrum disorders

Authors: *S. GRABRUCKER[1], G. EHRET[2], T. M. BOECKERS[3], A. M. GRABRUCKER[4]; [2]Neurobio., [3]Anat. and Cell Biol., [4]Neurol., [1]Ulm Univ., Ulm, Germany

Abstract: Autism Spectrum disorders (ASD) are neurodevelopmental disorders characterized by impairments in communication and social behavior, and by repetitive behaviors. ASD is considered to be a multi-factorial disorder resulting from genetic and non-genetic risk factors and their interaction. As genetic factors of ASD, mutations and deletions in SHANK genes have been identified that interfere with synaptogenesis and synapse function. However, ASD are also influenced by a variety of environmental, and possibly immunological factors that act during critical periods of brain development. The interaction of environmental exposures in the context of an individual's genetic susceptibility may manifest differently in each case and thus may be responsible for the heterogeneous phenotypes and varied comorbidities within the disorder. Here, using mouse models, we show that maternal zinc status as risk factor for ASD intersects with the SHANK pathway and the deregulation of any of these two factors may modify the behavior of the offspring leading to ASD. In particular, our data show that low postsynaptic zinc availability impacts the activity dependent regulation of Shank2 and Shank3 at the synapse and that a loss of synaptic Shank2 and Shank3 occurs in a mouse models for prenatal zinc deficiency. Zinc is one of the most prevalent metal ions in the brain and participates in processes such as neurogenesis, neuronal migration and differentiation, thereby shaping brain development and function. Similar to SHANK KO mice, prenatal zinc deficient animals displayed ASD related behavior later in life such as deficits in vocalization, increased aggression and slight abnormalities towards social stimuli and in social situations. Taken together, we suggest that part of the molecular underpinning of prenatal zinc deficiency as a risk factor for ASD may unfold through the

deregulation of zinc-binding Shank family members in the brain but also the gastro-intestinal system.

Inst. of NRCD, Tokorozawa, Saitama, Japan; [3]Japan Society for the Promotion of Sci., Chiyoda, Tokyo, Japan; [4]Dept. of Applied Biol. Sci., Tokyo Univ. of Sci., Noda, Chiba, Japan; [5]Dept. of Envrn. Hlth., Tokyo Univ. of Pharm. and Life Sci., Hachioji, Tokyo, Japan; [6]The Univ. of Electro-Communications, Chofu, Tokyo, Japan

Abstract: In human, when a rubber hand and a participant's hand are synchronously stroked by two brushes, a participant feels as if the rubber hand becomes his/her own hand (rubber hand illusion, RHI). We delivered the synchronous stroking to a rubber tail and a real tail of the mouse, and found that wild type mice responded (e.g., orienting or retracting the head) as if their own tails were being touched when the rubber tails were grasped (a RHI-like phenomenon in mice). From this discovery, we have developed a rubber tail task in mice, aiming to evaluate their body ownership. The RHI in human is known to be weak in persons with autism spectrum disorder (ASD). Thus, we examined whether the RHI-like phenomenon occurred in Ca^{2+}-dependent activator protein for secretion 2 knockout (CAPS2 KO) mice. The CAPS2 gene is known to involve in the release of brain-derived neurotrophic factor (BDNF), and its knockout (CAPS2 KO) mice show autistic-like phenotypes.
The CAPS2 KO mice (n = 5) and wild type mice (n = 13) were trained to stay in a small tube,

and were received daily tests under two conditions with two brushes: 1) synchronous stroking of a real tail and a rubber tail, 2) asynchronous stroking of both tails. After the tails were stroked for more than 1 minute, an experimenter firmly grasped the rubber tail, and responses of the mice were recorded and analyzed. A mean response rate over 10 days of testing in each condition was calculated.
Following the stroking, the response rates were significantly larger in the synchronous stroking condition (mean ± standard error, 0.41 ± 0.025), compared to the asynchronous stroking condition (0.26 ± 0.024), as previously reported in wild type mice. In contrast, there was no difference in the response rates between the synchronous (0.31 ± 0.033) and asynchronous (0.32 ± 0.035) stroking conditions in CAPS2 KO mice. Differences in response rates between conditions were significantly larger in the WT mice ($P < 0.001$, Wilcoxon rank sum test).
Our result suggests that the RHI-like phenomenon might not occur in CAPS2 KO mice. Dysfunctions in body ownership in ASD were partly simulated in the mouse model of ASD. Disorders in development of GABAergic interneuron network in CAPS2 KO mice may involve deficits in body ownership illusions in addition to the deficits in social communications.

Title: The effects of vagus nerve stimulation on abnormal emotional learning and social anxiety in an animal model of autism

Authors: *A. ALVAREZ-DIEPPA, S. CAVALIER, K. GRIFFIN, C. MCINTYRE;
Univ. of Texas At Dallas, Richardson, TX

Abstract: Administration of vagus nerve stimulation (VNS) during trials of fear extinction (VNS-paired extinction) enhances extinction of fear in healthy rats. Our studies show that VNS-paired extinction affects plasticity related proteins like CaMKII, Arc, and the GluN2B subunit of NMDA receptors in the basolateral complex of the amygdala (BLA; an area of the brain important for fear learning and social behaviors). Rats prenatally exposed to 500 mg/kg valproic acid (VPA-exposed rat) are used as an animal model of autism and they show impaired extinction of fear and diminished social interaction. We studied the potential of VNS to reverse fear extinction and social interaction impairments in rats that were prenatally exposed to VPA.

Male VPA-exposed and saline-control rats were subjected to auditory fear conditioning followed by extinction training that was paired with VNS or sham stimulation. Another cohort was exposed to a social interaction task during which entries to the social zone were coupled with VNS or sham stimulation. All groups showed the same level of conditioned fear after training. VPA-exposed rats given VNS during extinction training showed freezing levels that were similar to those of saline-control rats, and significantly lower than those of VPA-exposed rats given sham stimulation. VPA-exposed rats given VNS while in the social zone demonstrated higher preference for the social zone compared to VPA-exposed rats given sham stimulation, and showed a sociability index similar to that of saline-control rats. Western blot analysis revealed a significant decrease in phosphorylated CaMKII, Arc protein, and GluN2B expression in the BLA of VPA-exposed rats compared to saline-control rats. Results suggest that VNS-paired extinction can rescue extinction learning, and VNS-paired social interaction can alleviate social interaction deficits in VPA-exposed rats. Furthermore, abnormal CaMKII, Arc, and GluN2B expression in the BLA may underlie some of the cognitive deficits seen in the VPA-exposed rat model of autism.

Title: The behavioral expression and genetic regulation of repetitive and restricted behaviors in mice in the context of autism spectrum disorder

Authors: *R. T. MOLENHUIS[1], H. BRUINING[2], M. J. V. BRANDT[1], P. E. VAN SOLDT[1], J. P. H. BURBACH[1], F. A. IRAQI[3], R. MOTT[4], M. J. H. KAS[1];
[1]Translational Neurosci., [2]Psychiatry, Univ. Med. Ctr. Utrecht, Utrecht, Netherlands; [3]Sackler Fac. of Med., Tel Aviv Univ., Ramat Aviv, Israel; [4]UCL Genet. Inst., Univ. Col. London, London, United Kingdom

Abstract: Repetitive and restricted patterns of behavior are one of the predominant features of Autism Spectrum Disorder (ASD). They reflect reduced behavioral flexibility and inability to

adapt to novel situations. This behavioral domain is underrepresented in animal model studies of ASD. Here, we present novel assays of repetitive and restricted patterns of behavior in a mouse model of ASD and we test their genetic regulation using quantitative genetic mapping.
Repetitiveness in spontaneous exploratory behavior and locomotor-patterns was assessed in the BTBR T+tf/J mouse, an established behavioral model of ASD. A single-trial exposure to four novel objects showed that BTBR T+tf/J mice display a three-fold increase in the time spent in repetitive locomotor-patterns compared to C57BL/6J control mice as quantified by temporal pattern analysis of spatial bins of locomotor-activity. Significance was retained after correction for individual differences in locomotor activity ($p<0.001$).
We studied the genetic regulation of these behaviors using a novel mouse model population of human genetic diversity, the Collaborative Cross (CC). The quantitative expression of the novel object locomotor-patterns was highly variable and heritable. Quantitative trait locus (QTL) mapping in CC mice led to the identification of multiple genetic loci for different types of repetitive behaviors (genome-wide permuted $p<0.01$). Genetic loci for repetitive behaviors were partially linked to locomotor activity, suggesting that activity-levels and repetitive behaviors can have common but also differential genetic origins.
We show that unbiased analysis of locomotor patterns during novelty exposure can be used for quantitative analysis of restricted and repetitive behaviors. Using a combination of an established behavioral model of ASD and forward genetic analysis, we show that these phenotypes may be useful to dissect ASD's complex behavioral biology.

Title: Behavioral effects of an m_1 muscarinic cholinergic receptor agonist in the BTBR mouse model of autism

Authors: *M. E. RAGOZZINO[1], H. RAMIREZ[2], J. T. DUNN[2], W. S. MESSER, Jr.[3]; [2]Psychology, [1]Univ. of Illinois at Chicago, Chicago, IL; [3]Pharmacol. and Exptl. Therapeut., Univ. of Toledo, Toledo, OH

Abstract: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder characterized by social communication and interaction deficiencies along with restricted interests and repetitive behaviors (RRBs). RRBs can include an insistence on sameness or behavioral inflexibility, as well as repetitive, stereotyped behaviors. At present, there are no approved treatments to alleviate RRBs in ASD. Results from post-mortem studies suggest that brain muscarinic cholinergic receptor activity may be reduced in ASD. Thus, treatment with a muscarinic cholinergic receptor agonist may be effective in alleviating core symptoms in ASD. A recent study with BTBR mice, an idiopathic model of ASD, found that treatment with a non-specific, muscarinic cholinergic receptor agonist reduced repetitive behaviors including self-grooming and marble burying. Unknown is whether targeting specific muscarinic receptor subtypes would be sufficient to attenuate repetitive behaviors in BTBR mice. Treatment with a partial M_1 muscarinic receptor agonist was shown recently to improve behavioral flexibility in rats. Thus, targeting M_1 muscarinic receptors may be effective in reducing behavioral flexibility deficits and increased stereotyped repetitive behaviors in BTBR mice. The present study tested whether treatment with the partial M_1 muscarinic cholinergic receptor agonist, CDD-0102A, was sufficient to alleviate a reversal learning deficit and elevated grooming behavior in BTBR mice. As observed previously, BTBR mice exhibited elevated grooming and a reversal learning deficit compared to that of B6 mice. CDD-0102A at a 0.01 or 0.06 mg/kg dose (i.p.) did not attenuate elevated grooming behavior in BTBR mice. In contrast, CDD-0102A at 0.06 mg/kg did attenuate a reversal learning deficit in BTBR mice by reducing regressive errors. These findings suggest that treatment with an M_1 muscarinic cholinergic receptor agonist may be effective in treating cognitive flexibility deficits in ASD, but may not be effective in treating stereotyped repetitive behaviors.

Title: Atypical behavioral and neural phenotypes in a non-human primate model of autism spectrum disorders

Authors: *K. MIMURA[1,2,3], C. SATO[2], K. NAKAGAKI[1], I. AOKI[2], T. MINAMIMOTO[2], N. ICHINOHE[1,2];
[1]Dept. of Ultrastructural Res., Natl. Ctr. of Neurol. and Psychiatry, Tokyo, Japan; [2]Natl. Inst. of Radiological Sciences, QST, Chiba, Japan; [3]Japan Society for the Promotion of Sci., Tokyo, Japan

Abstract: Autism spectrum disorder (ASD) is a group of behaviorally defined neurodevelopmental disorders associated with social and cognitive disablities. In rodents, valproic acid (VPA) exposure *in utero* is widely used to an ASD model (Shin, 2015) because of its obvious surface fidelity. VPA has been reported as a risk factor of ASD in human clinical studies (Christensen, 2013). We reported VPA exposed ASD model in non-human primate, common marmoset (*Callithrix jacchus*) focused on abnormal psychiatric behavior in adulthood (Yasue, 2015). Here we show brain structural and behavioral phenotypes in early developmental stage of this model.
VPA exposed models of marmoset were obtained from the dams, which recieved 7 oral administrations of VPA at 200 mg/kg.day from 60 to 66 after conception.
Brain imaging study was conducted using 19 neonatal marmosets (P2 days of age, 9 VPA exposed, 10 unexposed; UE). Diffusion tensor images (DTI) were acquired using a 7 Tesla MRI system (20 cm bore, Bruker Biospin, Germany) in the *ex vivo* neonatal brain (TR/TE = 6500/26.56 ms, FOV = 32 × 32 mm^2, matrix size = 192 × 192, slice thickness = 1.0 mm, b value = 1000 s/mm^2, 30-direction). The corpus callosum (CC) and the anterior commissure (AC) were detected at mid-sagittal plane, and their sizes were measured by using Canny edge detection algorithm. In the mid-sagittal plane, neonatal VPA marmoset brains showed tendency that the AC was smaller than unexposed group. There have been no reports describing neonatal CC/AC structures with ASD even if in animal models. But bilateral hemispheric connection of human ASD patients, except neonate, were pepeatedly exxamined and shown to be weaker than that of normally grown human.
Behavioral study was conducted using 14 young marmosets (P30-150 days of age, 7 VPA, 7 UE) and their parents. To evaluate the kinship social communication, family (one juvenile and its parents) vocalizations were recorded for 30 minutes in their home cage carried at shield room. Vocal spectrogram was used to define and count 7 call types. As a result, in VPA families, “trill” call frequency, supposed ‘felling affinity’, was significantly decreased especially in ranging period (around 90 days of age). So, it is suggested that such abnormality of affinitive kinship communication in early life event could be translatable index of social disability between model animal and human cases.

Title: Neonatal RU-486 exposure; a gender specific animal model for the low maternal progesterone hypothesis of autism.

Authors: *H. GARMAN[1], J. KASS[2], S. KWON[3], R. MALSKY[3], C. INFANTINO[3], P. WHITAKER[4];
[2]Psychology, [1]Stony Brook Univ., Stony Brook, NY; [3]Psychology, [4]Integrative Neurosci. in Psychology and Psychiatry, Stony Brook Univ., Stonybrook, NY

Abstract: Progesterone is a sex hormone involved in maintaining a healthy pregnancy as well as having specific effects on the developing fetal brain. Low progesterone-associated obstetrical complications (bleeding, miscarriage and infertility) are increased in autism and thus it may be that the low progesterone itself is what also causes the brain changes which have been observed in autism. Males and females express progesterone receptors during different time periods in early development and if progesterone is involved, sexually dimorphic effects should be seen dependent on the critical periods when progesterone is active. Here, we test two models of low maternal progesterone, using the progesterone antagonist, RU-486 (40 mg/kg), and subcutaneous injections on postnatal days 1, 2 and 5 (**MPR**; associated with **M**ale **P**rogesterone **R**eceptor expression in the hypothalamus) or on postnatal days 7, 9 and 11 (**FPR**; associated with **F**emale **P**rogesterone **R**eceptor expression in hypothalamus). Sprague Dawley rats were divided into three groups (n=20 for each). Physical, repetitive, social, and motor development was observed. Early developmental markers showed a marginally delayed righting reflex for the MPR injection group compared to the control and FPR ($t = 1.82$, $p < 0.08$). Consistent with our pilot study, negative geotaxis was delayed on post-natal day 8 for both the MPR ($t = 2.31$, $p < 0.03$) and FPR groups, with the FPR group showing the most delay ($t = 4.67$, $p < 0.00$). Interestingly, only the MPR group displayed more unproductive motor movements on postnatal day 8 ($t = 2.08$, $p < 0.05$). Repetitive behaviors were increased in females from the FPR group ($t = 3.13$, $p < 0.01$) and males from the MPR group compared to their respective control ($t = 2.23$, $p < 0.05$). Deficits in social bonding with the mother were found in the females of the FPR group compared to the control group ($t = 3.33$, $p < 0.01$). Interestingly, the males in the MPR group showed more irregular maternal bonding behavior by leaving the mother more often than the control group (this was not seen in the FPR group, $t = 2.71$, $p < 0.01$). In a social choice paradigm, males from the MPR group showed deficits in social contact compared to control ($t = 3.12$, $p < 0.01$), females from the FPR group showed marginal deficits in social contact compared to control ($t = 1.91$, $p < 0.09$). Our results show that maternal progesterone at critical periods contributes to the

gender differences of ASD. These results suggest a disruption in the neuroendocrine system leading to changes in physical development, motor, social and repetitive behavior.

Title: Continuous activation of dopaminergic system improves autism-related behavioral abnormalities in mice prenatally exposed to valproic acid.

Authors: *S. HASEBE[1], Y. HARA[2], M. HIGUCHI[2], Y. AGO[2], T. NAKAZAWA[1,2], H. HASHIMOTO[2,3], T. MATSUDA[2], K. TAKUMA[1,3];

Abstract: Dosing of valproic acid (VPA), a widely used antiepileptic drug, during pregnancy has been reported to increase the risk of autism spectrum disorders (ASD) in children. We have recently demonstrated that mice prenatally exposed to VPA on embryonic day 12.5 provide a suitable animal model to study ASD (Hara et al., J. Pharmacol. Sci., 2012; Kataoka et al., Int. J. Neuropsychopharmacol., 2013; Takuma et al., Pharmacol. Biochem. Behav., 2014; Hara et al., Behav. Brain Res., 2015). In the present study, we examined whether the attention deficit/hyperactivity disorder (ADHD) treatment drugs methylphenidate and atomoxetine, which increase the extracellular levels of dopamine and noradrenaline in the prefrontal cortex of mice (Koda et al., J. Neurochem., 2010), could alleviate ASD-like behavioral abnormalities and a decreases in cortical dendritic spine density in the mice prenatally exposed to VPA. Pregnant ICR mice were intraperitoneally injected with either 500 mg/kg of VPA or saline on day 12.5 of

gestation. After birth, the offspring were weaned, sexed, and caged in groups of 5-6 mice of the same sex at 3 weeks old. Although acute administration of methylphenidate and atomoxetine increased prefrontal dopamine and noradrenaline release in the prenatal VPA-exposed mice at 8 weeks of age, it did not affect social interaction deficits and recognition memory impairment in VPA-exposed mice. In contrast, chronic administration of methylphenidate (3 mg/kg) and atomoxetine (1 mg/kg) for 2 weeks alleviated the ASD-like behavioral abnormalities. The chronic administration of the drugs also improved the decrease in dendritic spine density in the prefrontal cortex of the prenatal VPA-exposed mice. The ameliorative effects by chronic administration of the ADHD drugs on behaviors and dendritic spine morphology were blocked by the dopamine-D_1 receptor antagonist SCH39166 or the dopamine-D_2 receptor antagonist raclopride, but not by the α_2-adrenoceptor antagonist idazoxan. These findings suggest that chronic administration of methylphenidate and atomoxetine improves abnormal behaviors and diminishes the reduction in spine density in the mouse model of ASD through continuous activation of dopaminergic system.

Title: Neonatal treatments with risperidone partially reverses aberrant striatal compartmentation and ultrasonic vocalizations in a mouse model of autism spectrum disorder

Authors: H.-Y. KUO, *F.-C. LIU;
Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: Human studies have reported that children with maternal exposure to valproic acid (VPA) have a high risk of developing autism spectrum disorder (ASD). Animal studies have shown that maternally VPA-treated rat offspring develop ASD-like behaviors, including stereotypic and abnormal social behaviors that are related to striatal function. We have previously found abnormal striatal compartments in maternally VPA-treated mice (Kuo et al.,

2013). Risperidone, a dopamine D2 receptor antagonist, is a FDA-approved clinical drug for treating ASD patients. Here, we tested if risperidone could rescue defective striatal compartments and improve ASD-like symptoms in $VPA^{E12.75}$ mouse offspring. The VPA- and saline-treated mouse offspring were daily injected with risperidone or its vehicle from P0 to P7. The pups were then assayed for ultrasonic vocalizations (USV) at P8. Risperidone treatments significantly reversed the duration within each call in $VPA^{E12.75}$ mice compared to vehicle-treated $VPA^{E12.75}$ mice, but it had no effects on other USV features. Correlating with the improvement in USV duration by risperidone, an increase in MOR1-positive striosomal area in the rostral striatum was found in risperidone-treated $VPA^{E12.75}$ mice compared to vehicle-treated $VPA^{E12.75}$ mice. Risperidone did not alter MOR1-positive areas in the middle and caudal striatum. The reduction of MOR1-positive striosomes in $VPA^{E12.75}$ striatum was associated with a failure of aggregation $BrdU^{E12.75}$-labeled cells into striosomal patches. We found that the risperidone treatments were able to partially restore clusters of $BrdU^{E12.75}$ cells in $VPA^{E12.75}$ striatum compared to the vehicle-treated group, though the number of $BrdU^{E12.75}$-labeled cells was not changed. Taken together, our study suggests that the VPA-induced USV deficits are at least partially rescued by risperidone treatments, which is correlated with partial restoration of striosomal compartment. This work was funded by MOST104-2321-B-010-022, MOST104-2311-B-010-010-MY3.

Title: Autism-related behavior in juvenile and adult mice following perinatal antidepressant exposure

Authors: C. M. BOND, *N. S. WOEHRLE;
Psychology Dept., Wittenberg Univ., Springfield, OH

Abstract: Studies show an association between maternal antidepressant use during pregnancy and nursing and autism spectrum disorders in offspring (Croen et al., 2011, Rai et al., 2013). Thus, animal studies are needed to examine the role perinatal antidepressant exposure plays in the development of autism-related traits. The social symptoms of autism include deficient

reciprocal social interactions and reduced interest in novel social settings, and the presence of similar traits in mice can be measured by the three-chamber social test (TCST; Moy et al., 2004). Moreover, reduced non-selective attention is an associated feature of autism, and average rearing duration is thought to provide an index of non-selective attention in rodents (DeLorey et al., 2008, Aspide et al., 2000).
In this study, we perinatally exposed mice to a selective-serotonin reuptake inhibitor antidepressant by administering fluoxetine (18 mg/kg/day in the drinking water) to breeders from the time of pair-mating through weaning. We examined offspring as juveniles (3 weeks old) and adults (6 weeks old) for sociability and preference for social novelty behaviors in the TCST, and locomotor and rearing behaviors in the open field.
We found that male and female mice exposed to fluoxetine perinatally exhibit deficits in sociability and social novelty-seeking as juveniles, and these autism-like behaviors persist into adulthood. We also found that perinatal fluoxetine exposure produces hypoactivity and increases average rearing duration. Our findings suggest that perinatal fluoxetine exposure induces long-lasting social and attention deficits.

Title: Autistic-like behaviors with hyperactivity in mice lacking kirrel3

Authors: *T. HISAOKA[1], T. KOMORI[1], H. GYOBU[1], T. KITAMURA[2], Y. MORIKAWA[1]; [1]Dept. of Anat. & Neurobiology, Wakayama Med. Univ., Wakayama, Japan; [2]Div. of Cell. Therapy, Advanced Clin. Res. Ctr., The Inst. of Med. Science, The Univ. of Tokyo, Tokyo, Japan

Abstract: We have reported that a member of the immunoglobulin superfamily, kirrel3, is expressed in the brain, including the striatum, hippocampus, and cerebellum, using *in situ* hybridization histochemistry. Bhalla et al. (Am J Hum Genet 83: 703, 2008) have reported that a patient with severe intellectual disability shows *KIRREL3* mutation. Recently, a deletion of chromosome 11 that includes *KIRREL3* gene has been reported in a patient with autism spectrum

disorders (ASDs) associated with Jacobsen syndrome (Guerin et al., Am J Med Genet 158A: 2551, 2012), suggesting that *KIRREL3* gene is a candidate for ASDs. By whole-genome sequencing of monozygotic twins with ASDs, three de novo point mutations of *KIRREL3* gene have been identified (Michaelson et al., Cell 151: 1431, 2012). However, it remains unclear how the disruption of *kirrel3* gene causes these neurodevelopmental disorders.
To gain insights into the role of kirrel3 in the brain, we first investigated the localization of kirrel3 protein using immunohistochemistry. The localization of kirrel3 protein was observed in the hippocampal mossy fiber terminals and the cerebellar basket cell terminals as well as in the synaptic glomeruli of olfactory and accessory olfactory bulb. These results suggest that kirrel3 may be involved in the synapse formation and synaptic plasticity of the specific circuits, including the hippocampal and cerebellar circuits.
To further elucidate the role of kirrel3 in the brain, we generated *kirrel3*-knockout (*kirrel3*$^{-/-}$) mice and investigated their behavioral phenotype. In the 3-chamber social interaction test, *kirrel3*$^{-/-}$ mice displayed normal social interaction, but impairment of social novelty. Social communication by ultrasonic vocalization was reduced in adult *kirrel3*$^{-/-}$ mice. In the open field test, *kirrel3*$^{-/-}$ mice showed increased locomotor activity and stereotyped peripheral circling. In the acoustic startle test, enhanced startle response to acoustic stimuli was observed in *kirrel3*$^{-/-}$ mice. Thus, *kirrel3*$^{-/-}$ mice exhibited the communication/social deficits, stereotyped behavior, and sensory abnormality (auditory hyperreactivity) in addition to the hyperactivity behavior, which are relevant to ASDs with attention deficit hyperactivity disorder.

Title: Stereological investigation of the rat thalamic nuclei following developmental hyperserotonemia.

Authors: *L. HOUGH, R. FOREMAN, C. GRUBB;
Biomed. Sceinces, Missouri State Univ., Springfield, MO

Abstract: Elevated blood serotonin in perinatal development (Developmental Hyperserotonemia) is the most consistent neurochemical finding reported in Autism Spectrum Disorder (ASD), and has been implicated in the pathogenesis of the disorder. Accordingly, pre- and postnatal administration of the non-selective serotonin agonist, 5-methoxytptamine (5-MT), has been hypothesized as a model of developmental hyperserotonemia (DHS) to investigate the behavioral and morphological implications in ASD. Our previous study, examining the effects of DHS found significant neurodevelopmental changes in the dendritic architecture and synaptic connectivity of neurons in the dentate nucleus of the cerebellum. The present investigation has gone further to describe alterations in the development of the dentate-thalamo-cortical pathway, a neural network involved in motor learning, automaticity of movements, and higher cognitive functions, shown to be affected in ASD. Using unbiased stereological techniques, serial sections of DHS rats were compared to age-matched controls, specifically analyzing the effects of treatment on nuclear volume, and estimated cell number, area, distribution, and volume within the principle (relay) nuclei of the thalamus. Results did not show a change in the overall volume of the thalamus or the principle nuclei. However, there were significant differences in the relationship between thalamic volume and total brain volume (TBV). When grouped by estimated TBV, mean thalamic volume was significantly reduced in the DHS group relative to controls. Additionally, significant reductions in cell numbers, density and distribution were observed in some subdivisions of the principle nuclei including the ventral anterior (VA), ventral lateral (VL), ventral posterolateral (VPL), and ventral posteromedial (VPM) nuclei. The thalamus forms a key component of neural systems, with reciprocal connections to virtually every major region of the brain. Alterations in these connections and neuronal organization may be implicated in the neuropathological and behavioral changes observed in ASD.

Title: Dietary docosahexaenoic acid alleviates autistic-like behaviors resulting from maternal immune activation in mice

Authors: ***M. J. WEISER**[1], B. MUCHA[2], H. DENHEYER[2], D. ATKINSON[2], N. SCHANZ[2], E. VASSILIOU[3], R. H. BENNO[2];

[1]Biol. Models, DSM, Boulder, CO; [2]William Patterson Univ., Wayne, NJ; [3]Kean Univ., Union, NJ

Abstract: The prevalence of autism spectrum disorders over the last several decades has risen at an alarming rate. Factors such as broadened clinical definitions and increased parental age only partially account for this precipitous increase, suggesting that recent changes in environmental factors may also be responsible. One such factor could be the dramatic decrease in consumption of anti-inflammatory dietary omega-3 (n-3) polyunsaturated fatty acids (PUFAs) relative to the amount of pro-inflammatory omega-6 (n-6) PUFAs and saturated fats in the Western diet. Docosahexaenoic acid (DHA) is the principle n-3 PUFA found in neural tissue and is important for optimal brain development, especially during late gestation when DHA rapidly and preferentially accumulates in the brain. In this study, we tested whether supplementation of a low n-3 PUFA diet with DHA throughout development could improve measures related to autism in a mouse model of maternal immune activation. We found that dietary DHA protected offspring from the deleterious effects of gestational exposure to the viral mimetic polyriboinosinic-polyribocytidilic acid on behavioral measures of autism and subsequent adulthood immune system reactivity. These data suggest that elevated dietary levels of DHA, especially during pregnancy and nursing, may help protect normal neurodevelopment from the potentially adverse consequences of environmental insults like maternal infection.

Title: Valproic acid induction of nrf2 in fetal but not adult brain

Authors: *J. GIFFORD[1], S. NORTON[2], A. KUSNECOV[2], G. C. WAGNER[2];
[1]Rutgers Univ., Piscataway, NJ; [2]Psychology, Rutgers Univ., New Brunswick, NJ

Abstract: Autism is associated with high levels of oxidative stress biomarkers, increased body burdens of environmental toxicants that induce oxidative stress, and decreased levels of

antioxidants. A master regulator for the induction of the antioxidant response is the transcription factor, NRF2. Here we measured NRF2 expression as an indicator of an oxidative stress response following administration of valproic acid (VPA) to pregnant C57BL/6 mice. In adults, VPA is used as a GABAergic anticonvulsant and mood stabilizer. However, exposure *in utero* to VPA results in an autism-like syndrome. This differential response has been attributed to the GABA receptor activation being excitatory during early development, after which there is a shift to its recognized inhibitory function. This GABAergic shift in action is predicted to result in a differential oxidative stress response in the embryo (excitatory) relative to the dam (inhibitory). VPA (300 mg/kg, s.c.) was administered to pregnant mice on E12.5 and brain tissue was examined 2 hours later to determine if NRF2 protein expression was altered in either the dam and/or the embryos. Tissue was extracted and protein separated using SDS-PAGE gels. The membrane was then probed for NRF2and α-tubulin (Cell Signaling Technologies). Results were expressed as protein target ratio to α-tubulin. It was found that VPA increased NRF2 protein levels in the embryonic brains, but not in the brains of dams. The induction of embryonic NRF2 is likely a protective mechanism to defend against oxidative stress and suggests that VPA may be a risk factor for neurodevelopment during the prenatal period at a time when the GABAergic system is excitatory. This is consistent with previous data from our laboratory that showed VPA treatment altered a variety of behaviors that mark normal developmental milestones. This included alterations in motor reflexes and social investigation. Further, the toxicity exerted by VPA in the embryo may be through excitotoxic-engendered oxidative stress mechanisms.

Title: The effects of fastigial nuclei inactivation on social behavior in the rat

Authors: *V. K. BEHNKE, M. E. STEVENSON, H. E. HOBSON, J. R. KRUEGER, V. G. BELTRONE, A. S. NAZARIO, R. A. SWAIN;
Univ. of Wisconsin-Milwaukee, Milwaukee, WI

Abstract: Autism and autism spectrum disorders are developmental disabilities caused by brain abnormalities. These disorders affect more than one percent of the population (Minshew &

Williams, 2007). Recent research has implicated the cerebellum and its deep nuclei in autism. The dentate nuclei function in spatial processing and motivation (Joyal, Strazielle, & Lalonde, 2001), and the interpositus nuclei facilitate conditioning and learning (Christian & Thompson, 2003). The function of the fastigial nuclei, however, is more ambiguous. The present study examined the fastigial nuclei's role in mediating social interaction. The experiment questioned whether damage to the fastigial nuclei in rats would result in behaviors that could model the abnormal social behaviors seen in people with autism. Bilateral cannulation surgery was performed on 15 Long-Evans hooded rats. A within-subjects ABABAB reversal design was implemented. All animals received a microinfusion of saline during the A phases as baseline measures for social interaction. Social interactions were tested using a unique social interaction chamber and an open field with a confederate animal simultaneously occupying the apparatus. During the treatment phase, half of the animals received microinfusions of the anesthetic drug bupivacaine, which temporarily inactivated the fastigial nuclei. The other half received saline again and served as a control group. Social interaction was tested again for the treatment phase. This sequence was executed three times over a total of six days to achieve an ABABAB design. Social contact between the experimental and confederate animals was measured using multiple dependent variables, which allowed for delineation of the type of contacts in which the animals engaged. Results showed no difference in quantitative social interactions, but showed numerous significant differences in qualitative social interaction. Animals with inactivated fastigial nuclei engaged in more contacts with their body, but fewer contacts using their nose. This suggests animals with inactivated fastigial nuclei engaged in less intense and more passive social interactions. These animals also engaged in more behaviors to prevent social interaction. Similarly, people with autism engage in less intense, more passive, and more preventative behaviors than people without autism. This suggests animals with inactivated fastigial nuclei model some of the abnormal social behaviors seen in autism. Knowledge that the fastigial nuclei mediate the quality of social interactions can lead to breakthroughs in autism treatments and further the understanding of pathology in the autistic brain.

Title: Developmental exposure to the selective serotonin reuptake inhibitor citalopram alters spatial learning and memory, anxiety, sociability, and acoustic startle response in the offspring of Sprague-Dawley rats as adults

Authors: *J. NELMS SPROWLES[1], J. R. HUFGARD[2], A. GUTIERREZ[2], R. A. BAILEY[2], S. A. JABLONSKI[1], M. T. WILLIAMS[1,2], C. V. VORHEES[1,2];
[1]Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH; [2]Col. of Med., Univ. of Cincinnati, Cincinnati, OH

Abstract: Depression is widespread, and women are more likely to be affected, with the highest rate of occurrence during child-bearing years. Selective serotonin reuptake inhibitors (SSRIs) are commonly prescribed to women during pregnancy and the postpartum period. Thus, thousands of children are exposed to these serotonergic drugs *in utero* each year. SSRIs block the serotonin reuptake transporter (SERT) to increase synaptic 5-HT. Therefore, SSRIs may interfere with normal serotonergic modulation of development and impact brain ontogeny and behavior. Epidemiological studies report increased prevalence of autism spectrum disorder (ASD) in children whose mothers took SSRIs while pregnant (Boukhris et al., 2016; Croen et al., 2011). Studies in rodents have reported increased depression and anxiety-related behavior, decreased aggression and sociability, and impaired cognition following developmental SSRI exposure. The present study investigated whether pre- and neonatal exposure to citalopram influences behavioral outcomes. Sprague-Dawley dams were assigned to one of two treatment groups: Citalopram (10 mg/kg; CIT) or Saline (Sal). Dams were treated by subcutaneous injection twice daily (6 h apart) from E6-21, and pups were dosed from P1-20. Behavioral testing began on P60. One male/female pair from each litter was tested in the Cincinnati water maze for egocentric learning. Another pair received the Morris water maze to assess allocentric learning and memory. A third pair received elevated zero maze, open-field, marble burying, acoustic startle response with prepulse inhibition (PPI), social preference, and forced swim. There was no effect of treatment on swimming ability. Analyses showed significant treatment effects in Morris water maze acquisition (CIT rats had reduced path efficiency than Sal rats, $p \leq 0.01$), reduced open-field exploration ($p \leq 0.05$), increased marble burying ($p \leq 0.001$), increased PPI ($p \leq 0.01$), and reduced social preference ($p \leq 0.05$), but no changes in egocentric learning. The results suggest that developmental SSRI exposure results in enduring changes in behavior in the adult offspring consistent with an ASD-like phenotype.

Abstract: Deletion of chromosomal region 16p11.2 has been reported in approximately 0.6% of autism cases (Weiss et al., 2008; Hanson et al., 2010). 16p11.2 deletion syndrome is associated with developmental delay, intellectual disability, macrocephaly, obesity, language impairments and social deficits (Hanson et al., 2010; Shiwany et al., 2010; Hanson et al., 2015). R-baclofen, a GABA-B receptor agonist, was previously found to improve social and cognitive deficits in the *Fmr1* mouse model of Fragile X syndrome, (Henderson et al., 2012; Qin et al., 2015), and to reduce repetitive self-grooming and improve sociability in the BTBR mouse model of autism (Silverman et al., 2015). To evaluate the behavioral effects of r-baclofen in 16p11.2 deletion mice, we administered r-baclofen chronically in home-cage drinking water (0.5 mg/ml) to the Dolmetsch line of 16p11.2 heterozygous deletion mice and to their wildtype littermates. Control mice of each genotype received untreated drinking water. Subject mice were housed by sex in mixed genotype cages. To evaluate cognitive ability, we conducted the object location memory task using standard methods, with a one hour interval between habituation and testing as previously described (Yang et al., *Learning and Memory*, 2015). 16p11.2 heterozygotes failed to display significant object location memory. R-baclofen reversed this cognitive deficit. No differences in exploratory activity were detected during the habituation session. To evaluate sociability, we tested male-female reciprocal social interactions, as we had previously found that 16p11.2 male mice displayed fewer interactions with an estrous C57BL/6J female on some parameters (Yang et al., *Autism Research*, 2015). Videos were manually scored for male-female social interactions. Preliminary data suggest that r-baclofen treatment improved some parameters of social behaviors in 16p11.2 heterozygote males during male-female interactions. These findings support the hypothesis that Arbaclofen may offer an effective therapeutic for treating

some of the symptoms of 16p11.2 deletion syndrome (Berry-Kravis et al., 2012; Erickson et al., 2014).

Title: The impact of maternal care on a female mouse model of Rett syndrome

Authors: *A. VOGEL CIERNIA[1], M. PRIDE[2], A. NORONHA[2], A. CHANG[2], D. YASUI[2], J. N. CRAWLEY[2], J. M. LASALLE[2];
[1]MMI, [2]Univ. of California Davis, Davis, CA

Abstract: Rett syndrome is a neurodevelopmental disorder caused by mutations in the gene encoding methyl CpG binding protein 2 (MeCP2) that occur in 1:10,000 female births. Rett syndrome is characterized by a period of normal development followed by regression at 6-18 months of age and the onset of severe motor impairments. *Mecp2* mutations in mice recapitulate many of the clinical features of Rett syndrome, but the majority of behavioral assessments have been conducted in male MeCP2 hemizygous null mice. Given that Rett syndrome is predominately found in girls, we assessed heterozygous *Mecp2* mutant female mice (*Mecp2*$^{-/+}$) in a behavior battery that included measures of anxiety (elevated plus maze, light-dark box), activity (open field), motor function (gait analysis, accelerating rotarod, beam walking), sociability (three chamber social approach), and cognition (object location and recognition memory). Prior work with *Mecp2*$^{-/+}$ mice suggested that symptom onset was delayed until 6-9 months of age; however, we observed deficits in motor behaviors and alterations in activity much earlier (6-7 weeks of age). In comparison, sociability and short-term memory were intact in the *Mecp2*$^{-/+}$ mice, suggesting that the motor impairments were the predominant phenotype of this model. We also assessed the impact of maternal care on behavioral outcomes in MeCP2$^{-/+}$ mice, since breeding necessitates *Mecp2*$^{-/+}$ dams that have known adverse maternal behaviors. Cross fostering within 24hrs of birth to a CD1 dam resulted in litters with significantly higher body weights post weaning independent of genotype, and surprisingly, the fostered MeCP2$^{-/+}$

mice continued to gain weight into adulthood at a rate significantly surpassing their wildtype littermates and non-fostered *Mecp2*$^{-/+}$ mice. The larger body weight of the fostered MeCP2$^{-/+}$ mice may have further impaired performance on several of the motor tasks. Future work will be needed to longitudinally examine the relationship between maternal care, body weight, and motor task performance in MeCP2$^{-/+}$ mice. Overall, our findings indicate that MeCP2$^{-/+}$ mice recapitulate many of the motor aspects of Rett syndrome earlier than previously appreciated and that environmental factors, such as maternal care, may impact the phenotype severity.

Title: Correction of cognitive and behavioral deficits in a 16p11.2 CNV mouse model by selective activation of $GABA_B$ receptors with r-baclofen

Authors: *L. J. STOPPEL, A. R. PREZA, A. J. HEYNEN, M. F. BEAR;
MIT, Cambridge, MA

Abstract: Human chromosome 16p11.2 microdeletion is the most common gene copy number variation (CNV) in autism, affecting an estimated 3 in 10,000 people. Caused by a single copy deletion of ~27 genes, people with 16p11.2 microdeletion syndrome often exhibit impaired communication and socialization skills as well as intellectual disability. Studies on animal models of human 16p11.2 microdeletion disorder have revealed morphological, behavioral and electrophysiological deficits. Moreover, recent evidence suggests that neuronal dysfunction downstream of metabotropic glutamate receptor 5 ($mGlu_5$) contributes to cognitive deficits in mouse models of 16p11.2 microdeletion disorder and may be a point of convergence in the synaptic pathophysiologies of this and other genetic causes of autism including Fragile X Syndrome. Recently, R-baclofen, a $GABA_B$ receptor agonist, was shown to correct many disease-related pathologies in a mouse model of Fragile X Syndrome including cognitive impairments, and has shown promising outcomes in clinical trials with patients with autism and Fragile X Syndrome. We investigated the efficacy of r-baclofen to treat cognitive deficits in heterozygous 16p11.2 deletion mice generated by Alea Mills' laboratory. We administered r-

baclofen chronically in the drinking water (0.5 mg/ml) in 8-12 week old group-housed heterozygous (df/+) and wild-type male littermates for 2 weeks prior to behavioral testing. We found that vehicle-treated df/+ mice exhibited profound deficits in a familiar object recognition task and contextual fear discrimination task, similar to previous reports. Additionally, we found that df/+ mice exhibit hyperactivity, spend more time in the center in the open field and fail to habituate across testing sessions. Importantly, chronic r-baclofen treatment corrected deficits in object recognition and contextual fear discrimination and restored normal habituation and behavior in the open field. Our results indicate that inhibition of $GABA_B$ receptors with r-baclofen may be a promising treatment avenue for patients with 16p11.2 microdeletion disorder and other genetic causes of autism with similar dysfunction.

Title: Testing two mouse models of 16p11.2 deletion syndrome in touchscreen learning and reversal tasks

Authors: *B. L. ONAGA[1], G. LIOW[2], M. S. SARVI[2], M. YANG[1];
[1]Psychiatry & Behavioral Sci., UCD Med. Ctr. & MIND Inst., Sacramento, CA; [2]Univ. of California Davis, Davis, CA

Abstract: Recurrent heterozygous deletions of a ~600kb segment on human chromosome 16 is found in ~0.4% of individuals with intellectual disabilities (ID) and 0.6% of cases of autism (Weiss et al., 2008; Hanson et al., 2015). 16p11.2 deletion is also associated with speech delay, developmental delays, psychiatric disorders, and obesity. The present study evaluated associative learning and cognitive flexibility in two mouse models of 16p11.2 deletion, the Dolmetsch, generated at Stanford University in the Dolmetsch Lab (Portmann et al., 2014), and the Mills line, generated by the Mills' Lab at Cold Springs Harbor (Horev et al., 2011). Previous studies reported impaired novel object recognition in heterozygous (+/-) mice of both lines (Portmann et al., 2014; Pucilowska et al., 2015). Impaired object location memory and social memory were detected in Dolmetsch +/- (Yang et al., 2015a). Deficits in contextual fear conditioning and passive avoidance were reported for the Mills line (Tian et al., 2015), but not in the Dolmetsch

line (Yang et al., 2015b). In this study we used the automated Bussey-Saksida touchscreen system for mice (Campden Instruments Ltd/Lafayette Instruments, Lafayette, IL, USA) to further examine cognitive phenotype deficits in both lines. We evaluated the basic pairwise visual discrimination and reversal learning tasks, as described previously (Silverman et al., 2015; Yang et al., 2015b). To further explore cognitive flexibility, we also pioneered a re-reversal task. In pre-training stages, there were no genotype differences in days to reach criterion for the Dolmetsch line. Similarly, +/- of the Mills line exhibited no deficits in pre-training. In the pairwise visual discrimination test, deficits were replicated in the Dolmetsch line +/- (Yang et al., 2015b), but were not detected in Mills +/-. In our novel re-reversal task, correct and incorrect images were again switched. All Dolmetsch wildtype (+/+) mice were able to reach criterion, whereas all but one +/- failed the reversal task and were not eligible for the re-reversal training. In comparison, all +/+ and +/- of the Mills line were advanced to, and were able to complete, the re-reversal task. In summary, we replicated pairwise visual discrimination impairments and cognitive inflexibility in the Dolmetsch +/-. Preliminary testing of the Mills line revealed no apparent deficits in pairwise discrimination, reversal, or re-reversal training. Future experiments will explore other aspects of cognitive functions, using transitive inference and paired-association learning.

Title: Evaluation of the TrkB agonist 7,8-dihydroxyflavone in the BTBR mouse model of autism

Authors: ***T. M. KAZDOBA**[1], P. T. LEACH[2], K. SISON[2], J. N. CRAWLEY[2];

Abstract: Dysregulation of brain-derived neurotrophic factor (BDNF) signaling is a possible contributing factor in autism spectrum disorders. BDNF, a member of the neurotrophin family of growth factors, is crucial for the growth and differentiation of new synapses and neurons as well as neuronal survival. BTBR T+tf/J (BTBR) mice, an inbred mouse strain that models idiopathic autism, display impaired sociability, excessive grooming and cognitive deficits (McFarlane et al.,

2008; Silverman et al., 2013; Yang et al., 2012). Reductions in BDNF signaling and mRNA, as well as levels of the BDNF TrkB receptor, have been identified in several brain regions in BTBR mice, as compared to the social strain C57BL/6 (B6) (Stephenson et al., 2011; Scattoni et al., 2013; Jasien et al., 2014). In the current set of studies, subchronic administration of the TrkB agonist, 7,8-dihydroxyflavone (7,8-DHF), was evaluated in BTBR and B6 mice to determine its effects on sociability and repetitive behaviors. Administration of 7,8-DHF was not detrimental to B6 social behaviors, as assessed by the 3-chambered social approach task and male-female reciprocal social interactions. BTBR mice administered 7.5 mg/kg 7,8-DHF i.p. spent significantly more time with the novel social mouse than with the novel cup. In addition, BTBR mice administered 2.5, 5, or 7.5 mg/kg 7,8-DHF spent significantly more time sniffing the novel social mouse compared to the novel cup. 7,8-DHF did not improve BTBR social behaviors in the male-female reciprocal social interaction task. 7,8-DHF did not have any significant effects on B6 or BTBR repetitive behaviors, and did not significantly affect open field locomotion. These data suggest that modulation of the BDNF signaling pathway may have modest effects on sociability.

Title: Touchscreen visual discrimination learning and water maze deficits in the Ts65Dn mouse model of Down syndrome

Authors: *P. T. LEACH[1,2], T. M. KAZDOBA[2], K. SISON[2], C. M. GALL[3], G. LYNCH[4], J. N. CRAWLEY[2];
[1]Psychiatry, Biogen, Cambridge, MA; [2]Psychiatry, Univ. of California Davis Sch. of Med., Sacramento, CA; [3]Dept. of Anat. and Neurobio., [4]Dept. of Psychiatry and Human Behavior, Univ. of California Irvine Sch. of Med., Irvine, CA

Abstract: Down syndrome, a leading genetic cause of intellectual disabilities, is caused by a trisomy of chromosome 21. Mouse studies of Down syndrome have frequently used the

homologous Ts65Dn mouse model, which displays deficits on some cognitive tasks including Morris water maze, fear conditioning, and novel object recognition (Costa, Stasko, Schmidt, & Davisson, 2010; Holtzman et al., 1996; Lockrow, Boger, Bimonte-Nelson, & Granholm, 2011). We tested cortically-dependent learning in Ts65Dn mice with a novel touchscreen-based operant task. Touchscreen cognitive assays are frequently used in human cognition testing, offering face validity and potential translational value for testing pharmacological and behavioral interventions. Food restricted WT and Ts65Dn male and female mice were trained on acquisition of a pairwise visual discrimination task, in which an X symbol and an = symbol of matched illumination were presented simultaneously on a touchscreen located at the front panel of the chamber. Image location alternated randomly between left and right image locations. Mice were pseudorandomly assigned to be rewarded for pressing the X versus the = image. Pressing the correct image was reinforced with 20 µl strawberry Ensure milkshake, while incorrect image touches were followed by a 20 sec timeout. Survival curves and unpaired t-tests revealed genotype differences on acquisition of the visual discrimination task. Ts65Dn took significantly more trials to reach criterion than WT (p=.01), and showed a strong trend for more days to reach criterion (p=.06) while there were no differences in the number of trials completed per day or on pre-training performance. Further, in a separate cohort of Ts65Dn and WT mice, we replicated Morris water maze spatial navigation deficits in learning the hidden platform location, confirming previous reports. Acquisition of the visible platform using proximal cues did not differ between genotypes, confirming normal visual and swimming abilities. These studies extend the range of cognitive phenotypes in the Ts65Dn mouse model of Down syndrome to a touchscreen assay with procedural methodologies analogous to standard human cognitive tests.

Title: Forebrain loss of active Met tyrosine kinase disrupts cortical connectivity and GABA signaling

Authors: S. TANG[1], S. XU[2], W. ZHU[2], F.-S. LO[3], R. S. ERZURUMLU[3], *E. M. POWELL[4]; [1]Grad. Program in Toxicology, [2]Diagnos. Radiology and Nuclear Med., [3]Anat. & Neurobio.,

Univ. of Maryland Sch. of Med., Baltimore, MD; [4]Anat/Neurobio, Univ. Maryland, Baltimore, Baltimore, MD

Abstract: *MET*, the gene encoding the tyrosine kinase receptor for hepatocyte growth factor/scatter factor (HGF), has been identified as a susceptibility locus for autism spectrum disorders (ASD). Genetically altered mice with a targeted kinase-dead *Met* expressed in the cerebral cortex and hippocampus (under the control of the *Emx1-cre* driver), offer a useful model for the human susceptibility alleles of *MET*. Our previous structural magnetic resonance imaging (MRI) studies demonstrated an expansion of the sensory, motor and frontal cortical regions. We report resting state functional MRI with the graph-analysis toolbox with 37 regions of interest defined for the mouse brain, to examine neuronal connectivity in heterozygous *Met-Emx1,* and fully inactive homozygous *Met-Emx1* mice, and controls. Global network measures, including small-world index, clustering coefficiency, local efficiency, transitivity, assortativity, and modularity, were significantly lower in heterozygous *Met-Emx1* mice compared to control mice. Regional measures of clustering coefficient, local efficiency, degree, and node betweenness were altered in both heterozygous and homozygous *Met-Emx1* mice compared to control animals. The changes indicated greater local connectivity and reduced long range interactions in *Met-Emx1* brains, consistent with reports in individuals with ASD and those harboring *MET* autism susceptibility alleles. Behavioral observations also indicate potential altered sensory processing in *Met-Emx1* mice. Imbalances in the ratio of excitation to inhibition have been cited as an underlying cause of autism and a phenotype in multiple animal models of ASD. Electrophysiology of layer IV somatosensory cortical neurons from *Met-Emx1* brains indicated reduced inhibition. Attempts to increase inhibition by recruiting additional GABA-A receptors to the neuronal membrane were unsuccessful in *Met-Emx1* cortex. The lack of sufficient GABA-A receptors led to the hypothesis of increased free extracellular GABA concentration. In vivo magnetic resonance spectroscopy (MRS) measurements of neurotransmitters demonstrate significant increased GABA concentration in male *Met-Emx1* mice, with no changes in female *Met-Emx1* mice. The MRS data support a new role for Met in regulating GABA concentration and availability in a sex-dependent manner.

Title: Ketogenic diets improve behaviors associated with autism spectrum disorder in the EL mouse

Authors: *D. N. RUSKIN, J. A. FORTIN, S. BISNAUTH, S. A. MASINO;
Trinity Col., Hartford, CT

Abstract: Attempts to ameliorate the core symptoms of autism spectrum disorder (ASD) with medications have had little success. Symptoms of ASD are frequently comorbid with a diagnosis of epilepsy and vice versa. Severe drug-refractory cases of comorbid ASD and epilepsy can have very poor outcomes, even with epilepsy surgery. Ketogenic diets (KDs) are remarkably effective treatments for epilepsy, and there is accumulating evidence for beneficial effects of ketogenic diets against core symptoms of ASD in animal models and patients. This study tests the behavioral effects of KD feeding in a murine model of comorbid ASD and epilepsy, the EL mouse strain. EL mice were fed control diet or one of two KD formulas ad libitum starting at 5 wk of age. Beginning at 8 wk of age, diet protocols continued and performance of each group on tests of sociability and repetitive behavior was assessed. Behavior was never worsened by a KD; results were mixed and generally positive depending on sex and type of test. KD feeding improved sociability and repetitive behavior under some conditions in female mice. In males, KD feeding did not significantly improve sociability, but did reduce self-directed repetitive behavior in a single-chamber test. Experiments with KDs of differing strength in female mice showed that a less strict, more clinically-relevant diet was fully effective. Behavioral improvements did not depend on a significant decrease in blood glucose; they might depend on ketosis although ketosis alone was not sufficient. Taken together these results add to the growing number of studies suggesting that KDs and related diets may provide significant relief from the core symptoms of ASD, and suggest there may be increased efficacy in females.

Title: Ketogenic diet improves decreased mitochondrial respiration and activities of electron transport chain complex I and pyruvate dehydrogenase in BTBR autistic mice

Authors: Y. AHN[1], N. YEE[1], R. TOBIAS[1], *J. M. RHO[2];
[1]Pediatrics, Univ. of Calgary, Calgary, AB, Canada; [2]Alberta Children's Hospital, Univ. of Calgary, Calgary, AB, Canada

Abstract: Autism spectrum disorder (ASD) is a highly prevalent neurodevelopmental condition (1/68 in United State) that is characterized by specific behavioral and cognitive impairments, and is believed to arise from heterogeneous causes. Although a single and unifying pathophysiological mechanism is unlikely, there is growing evidence that mitochondrial dysfunction may play a critical role in provoking behavioral symptoms.
The BTBR T+tf/J (BTBR) mouse is a robust model of ASD and displays all three core behavioral features compared to C57 mice. Earlier, it was shown that the ketogenic diet (KD) can reduce autistic behaviors in BTBR mice (PMID: 23755170).
Here, we hypothesize that impaired mitochondrial bioenergetics may contribute to the etiology of ASD and that behavioral improvements induced by the KD are associated with changes in mitochondrial metabolism. To demonstrate this, we measured the mitochondrial oxygen consumption rate (OCR) using the Seahorse Bioscience XF24 analyzer. We observed significantly lower OCR levels in BTBR mice than in C57 control mice ($p<0.001$, N=13/group), and the KD improved OCR levels in BTBR mice ($p<0.05$, N=13/group). To determine the underlying mechanism for the observed decreased mitochondrial respiration in BTBR mice, we measured the activities of two of the five mitochondrial electron transport chain (ETC) complexes (Complex I & II), and pyruvate dehydrogenase (PDH). The activity of complex I was significantly decreased in autistic mice compared to control mice ($p<0.05$, N=4~5/group) and PDH activity showed the attenuated trend but was not significant ($p=0.073$, N=4~5/group). The KD led to statistically-significant improvements in the BTBR mice ($p<0.05$ for complex I and $p<0.001$ for PDH). The activity of Complex II was higher in autistic mice than in C57 controls ($p=0.0562$, N=6/group) and was significantly attenuated by the KD ($p<0.01$, N=6/group). Collectively, these observations suggest that mitochondrial dysfunctions such as dysregulation of mitochondrial respiration and abnormalities of Complex I, II and PDH in the brain may be important contributors to the autistic phenotype of BTBR mice, that the ketogenic diet can improve these mitochondrial dysfunctions in ASD, and that this putative improvement derived from better OXPHOS management may affect behavioral symptoms. Thus, we anticipate that this data may provide further evidence that abnormalities in mitochondrial function may underlie in part the behavioral features of ASD, and that the ketogenic diet may have potential therapeutic use.

Title: Identification of circuits regulating socially-directed behavior using DREADD-fMRI.

Authors: *M. BENEKAREDDY[1], T. J. STACHNIAK[2], M. VON KIENLIN[2], B. KUENNECKE[2], A. GHOSH[3];
[1]Neuroscience, Ophthalmology & Rare Dis. (NORD) Translational Area, Roche Pharma Res. & Early Development, Roche I, Basel, Switzerland; [2]Neuroscience, Ophthalmology, & Rare Dis. (NORD) Translational Area,, Roche Pharma Res. & Early Development, Roche Innovation Ctr. Basel, Basel, Switzerland; [3]E-Scape Bio, San Francisco, CA

Abstract: Impairment in social function is one of the core deficits of autism spectrum disorder (ASD) and a prominent feature of schizophrenia (SZ). The neural circuit basis of impaired social function in disease states is only beginning to be understood with evidence pointing to an important role played by frontal cortical areas. In this study, using a combination of chemogenetics (Rogan and Roth, 2011), and rodent social behavior tasks, we assessed the consequences of altered neural activity in the prefrontal cortex on social behavior in rats and mice. To identify global circuit partners of the PFC and generate hypotheses about specific brain regions that act in tandem with the PFC in mediating social dysfunction, we performed a neuroimaging screen with magnetic resonance imaging (MRI) for brain-wide activity changes induced by the DREADD (Designer Receptors Exclusively Activated by Designer Drug) technology (Armbruster et al., 2007; Vardy et al., 2015). We further refined this functional PFC network by screening for co-regulations during bidirectional modulation of PFC activity. Acute activation of the prefrontal cortex using hM3D, the Gq coupled activating designer GPCR in excitatory neurons leads to a reversible decrease in sociability in both rats and mice. Chronic perturbation of PFC activity either by expressing hM3D in excitatory neurons or hM4D - the Gi coupled inhibitory designer GPCR - in parvalbumin or somatostatin inhibitory neuronal subtypes alters social function in a time-point and cell type dependent manner. In a further effort to investigate the brain-wide consequences of activating the prefrontal cortex, animals were subjected to MRI during acute activation of the prefrontal cortex. Prefrontal cortex activation led to a significant increase in blood perfusion in the prefrontal cortex (as expected), and led to the activation of brain regions like the nucleus accumbens, and dorsal raphe nucleus, known to be involved in the regulation of emotional behaviors. Our results lend further credence to the hypothesis that reciprocal connections between PFC and several key subcortical regions provide a circuit level framework for altered cortical and sub-cortical function to modify social behavior.

Title: Digging behavior discrimination: a new test you will dig

Authors: H. L. POND, J. ADELMAN, O. MCKISSICK, *M. MANZINI;
Pharmacol. and Physiol., The George Washington Univ., Washington, DC

Abstract: The marble burying test, where digging is measured as related to the number of marbles buried in deep bedding, has become a popular assay for anxiety, obsessive compulsive disorder (OCD), and most recently, for repetitive behaviors in mouse models of autism spectrum disorder (ASD). While digging intensity is used to test repetitive behaviors and anxiety, digging is also a normal mouse behavior, that can be focused toward different goals: foraging for food, burrowing for shelter, removing noxious stimuli, or even for recreation, as has been shown for dogs and ferrets. The marble burying test originated as a test to analyze species-specific defensive behaviors in rats. However, rat behaviors do not necessarily translate to mice. Mice do not actively bury the marbles and do not spend much time interacting or reacting to the marbles at all, suggesting that the number of marbles buried is incidental to digging activity. Here, we present the Digging Behavior Discrimination test, a new paradigm to obtain clear distinctions between different types of digging behavior in mouse models based on the driving motivation for each type of digging. We look at food-seeking digging behavior as well as burrowing digging behavior, and how these related to the presence of marbles. To distinguish between food-seeking digging behavior and burrowing digging behavior we set up a clear cage with ample amount of corncob substrate. In one corner is a transparent tube that is filled with paper bedding. Mice are then placed into the apparatus and monitored for 30 minutes to observe their behavior. Wild-type mice fed ad libitum are compared with food-deprived animals following 20-25% weight loss. Satiated mice are more motivated to burrow in a new environment and spend significantly more time in the burrowing area than the food-deprived mice. In addition, the food-deprived mice

spend more time in the open area digging than they do in the burrow. To make sure the difference was not just due to acclimatization to a new environment, we performed the test again on the food deprived mice two weeks after their food intake returned to ad libitum. Once they were satiated again, the mice switched behaviors spending more time in the burrowing area. In general, the mice are indifferent to the presence or absence of marbles in the apparatus. This indicates that laboratory mice display digging behaviors with specific motivations, while they perform digging tests. This novel test could be used to better understand animal models of neuropsychiatric disorders to probe brain circuits involved in motivation, food seeking, shelter/safety seeking and anxiety.

Title: Delayed and reduced baseline and social isolation-potentiated ultrasonic vocalization in neonatal fragile X knockout mice

Authors: ***B. ZUPAN**[1], S. R. M. DEWIL[2], L. MORSE[2];
[1]Psychology, [2]Neurosci. and Behavior Program, Vassar Col., Poughkeepsie, NY

Abstract: Silencing of the fragile X mental retardation (*FMR1*) gene causes Fragile X syndrome (FXS) and is the most common monogenic cause of autism. Symptoms shared by both neurodevelopmental disorders include cognitive inflexibility, hyperactivity and abnormal social behavior. Although the mouse model of FXS, the *fmr1* knock-out (KO) mouse, recapitulates a number of these symptoms, reports of abnormal social interaction and altered ultrasonic vocalization (USV) in both adult and neonate have been inconsistent. USV is an easily quantifiable measure of social communication and pup-dam interaction during early postnatal development, and abnormal vocalizations have been observed in mouse models of a number of neurodevelopmental disorders. Here we assessed USVs emitted by *fmr1* KO and wild-type (WT) neonate mice and found decreased call number and total call duration in both male and female KO but not WT pups at postnatal day (P) 4 and 8. Number of USVs did not change over time in WT mice, but KO pups showed an increase in vocalizations on P12 relative to P4 and 8, data suggestive of delayed onset of social communication in *fmr1* deficient pups. This interpretation

is further supported by the observation of alterated social isolation-potentiated vocalization (a modified maternal potentiation paradigm). Specifically, WT but not KO pups emitted increased number of calls following a five-minute social isolation at P4 and P12, while KO mice showed marginal potentiation at P8 only. Although maternal behavior can influence pup USVs, we observed no differences in maternal care between WT and KO dams. Taken together, our data suggest that the lack of *fmr1* may delay the temporal onset of social communication in the *fmr1* deficient neonate mouse and that this delay may be a marker of neurodevelopmental alterations underlying differences in adult social behavior. Indeed, in human, reduced and delayed onset of vocalization in infants is positively associated with subsequent diagnoses of neurodevelopmental disorders.

Title: Characterization of the behavioral phenotype and neuroinflammatory profile of the FMR1 KO mouse

Authors: *S. L. HODGES[1], S. O. NOLAN[2], C. REYNOLDS[2], G. D. SMITH[1], A. HOLLEY[2], T. JEFFERSON[2], J. HUEBSCHMAN[2], M. VOLQUARDSEN[2], A. PANDIAN[2], J. N. LUGO[3]; [1]Inst. of Biomed. Studies, [2]Psychology and Neurosci., [3]Psychology and Neuroscience, Inst. of Biomed. Studies, Baylor Univ., Waco, TX

Abstract: Fragile X syndrome (FXS) is a neurodevelopmental disorder characterized by a variety of behavioral, intellectual, and physiological abnormalities, caused by an expanded trinucleotide (CGG) repeat in the *FMR1* gene, leading to hypermethylation and subsequent functional silencing of expression of fragile x mental retardation protein (FMRP). In this current study, we examined social behavior, anxiety, locomotor activity, and repetitive behavior in adult male and female *FMR1* wild type (WT) and knockout (KO) mice on a FVB background strain. In comparison to WT mice, *FMR1* KO mice had significant increases in stereotypy time, rearing time, and total distance moved. The *FMR1* KO mice also displayed significant differences in anxiety, sociability, and learning. In addition to changes in the behavioral phenotype, recent studies have provided evidence of dysregulated cytokine and chemokine production in both

humans with FXS and mouse models indicating that an abnormal immune profile may also be associated with the syndrome. Increasing evidence has found elevated inflammatory markers and microglia dysfunction to be involved in the pathogenesis of autism, which is known to have a strong association with FXS. However, how this may relate to impaired behavioral outcomes is unknown. Following characterization of the behavioral phenotypes, we examined differences in neuroinflammatory markers, including IL-1β, TNF-α, and IL-10, as well as cell type expression in the hippocampus. With further characterization of the *FMR1* KO immune profile we hope to gain a better understanding of the potential pathogenic role of neuroinflammation in FXS and how this immune dysregulation may lead to the development of cognitive and behavioral deficits seen in the syndrome.

Title: The effects of dietary supplementation with n-3 fatty acids on behavioral and neuroinflammatory phenotype of the Fmr1-knockout mouse.

Authors: *S. O. NOLAN[1], S. L. HODGES[2], G. D. SMITH[2], T. JEFFERSON[1], B. ESCOBAR[1], A. J. HOLLEY[1], J. N. LUGO[1];

Abstract: Fragile X Syndrome (FXS) is a neurodevelopmental disorder caused by a genetic trinucleotide (CGG) overexpansion mutation in the fmr-1 gene coding for fragile x mental retardation protein (FMRP). This disorder is characterized by marked intellectual disability, as well as other autistic-like behavioral phenotypes. Supplementation with omega-3 polyunsaturated fatty acids (n-3 PUFAs) has been proposed as an alternative treatment for a variety of neurodevelopmental disorders, including autism spectrum disorder (ASD) and attention deficit hyperactivity disorder (ADHD). In the present study, male FVB/129 fmr-1 knockout and fmr-1 wildtype littermates were assigned to one of three diet conditions following weaning on PD21: standard lab chow, EPA/DHA enriched chow, and a diet controlling for the

increase in fat associated with the EPA/DHA diet. Upon reaching postnatal day 90, animals were tested in a several behavioral assays, which included open field, elevated plus maze, social partition, nose poke assay, delay fear conditioning and pre-pulse inhibition. Preliminary results revealed that the increased dietary fatty acid composition significantly impacted sociability and fear learning in a genotype-dependent manner. No differences were noted in anxiety or repetitive behaviors. Previous research has indicated that dietary composition can affect the composition of the gut microbiome, which has downstream impacts on behavior and inflammation. Therefore, subsequent gut microflora, as well as western blotting and immunohistochemical analyses were performed to investigate molecular substrates associated with dietary and phenotypic changes.

Title: Decrease of MMP-9 level in central amygdala rescues cognitive deficit in mouse model of fragile X syndrome

Authors: *A. PUSCIAN[1], S. LESKI[1], M. WINIARSKI[1], J. BOROWSKA[1], M. CHATURVEDI[1], J. SADOWSKA[1], H.-P. LIPP[2,3], E. KNAPSKA[1];
[1]Nencki Inst. of Exptl. Biology, PAS, Warsaw, Poland; [2]Inst. of Anatomy, Univ. of Zurich, Zurich, Switzerland; [3]Sch. of Lab. Medicine, Kwazulu-Natal Univ. Durban, Durban, South Africa

Abstract: Loss-of-function mutations in the Fragile X mental retardation protein (FMRP) result in Fragile X syndrome (FXS), which is the most wide-spread single-gene cause of autism. FXS is a trinucleotide repeat disorder in which a CGG element located within the 5' untranslated region of *FMR1* gene expands and becomes hypermethylated. In case of the complete silencing of *FMR1* gene male patients have an average IQ of 40 and cope with severe cognitive impairments and excluding learning disabilities.
In our studies we exploited a mouse model of FXS (*Fmr1* knockouts) mimicking above-described phenotype in humans. As FMRP is a major local-translation suppressor its lack leads to overexpression of many synaptic plasticity proteins. Among those matrix metalloproteinase-9

(MMP-9) is a crucial player in reward-motivated learning, specifically its proper level in central amygdala (CA) is required for mice' ability to discriminate between highly-motivating reward and neutral stimuli.
Using fully automated behavioral testing (IntelliCage system), which enabled us to investigate characteristics that can be observed only in a continuous, long-lasting study, we showed that *Fmr1* knockouts are unable to efficiently perform such discrimination tasks. However, downregulation of heightened MMP-9 level in central amygdala was sufficient to fully rescue this impairment. This effect was obtained by a local injection of nanoparticles gradually releasing selective MMP-9 inhibitor (TIMP-1). It is noteworthy, that nanoparticles are able to cross brain-blood barrier and thus the implemented paradigm holds promise of obtaining clinically relevant solutions for the most severely disabled FXS patients.

Title: Chronic sleep restriction in Fmr1 knockout and WT mice has long term effects on behavior

Authors: *R. M. SARE, A. SONG, M. LEVINE, C. HILDRETH, A. MFON, C. SHEELER, C. BEEBE SMITH;
Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Sleep abnormalities are prevalent in patients with neurodevelopmental disorders, including those with Fragile X Syndrome (FXS). Furthermore, the severity of sleep abnormalities correlates with the severity of behavioral impairments. FXS is caused by an expanded CGG repeat on the X chromosome resulting in silencing of the *FMR1* gene and loss of the protein product FMRP. The physical and behavioral phenotypes of Fragile X are recapitulated in the *Fmr1* knockout (KO) mouse model. The behavioral phenotypes include hyperactivity, reduced anxiety, and social behavior abnormalities.Given the association between

sleep abnormalities and behavioral impairments, we sought to investigate the effects of chronic sleep restriction during a critical developmental period in KO mice on behavior in adulthood. We sleep-restricted both WT and *Fmr1* KO mice from P5-P42 for 3 hr per day by gentle handling. Following chronic sleep restriction, animals were allowed a period of four weeks of recovery sleep, after which we measured behavioral outcomes. We assayed activity and anxiety in the open field, social behavior, repetitive behavior, total sleep time, and sleep bout duration. In WT mice, sleep restriction resulted in hypoactivity, increased anxiety, reduced preference for social novelty, and shorter sleep bouts. In *Fmr1* KO mice, sleep restriction resulted in hypoactivity and longer sleep bouts; anxiety-like behavior and social behavior were unaffected by sleep restriction. Developmental sleep restriction resulted in phase-dependent effects on total sleep time suggesting a disruption in circadian rhythm; theses effects occurred in both genotypes. Repetitive behavior was unaffected by sleep restriction in either genotype. These behavioral changes highlight the importance of sleep during development and indicate that the response to sleep restriction is influenced by the absence of FMRP.

Abstract: Fragile X syndrome (FXS), the leading single gene cause of autism and the most common form of hereditary mental retardation, is caused by the silencing of the *FMR1* gene and subsequent loss of fragile X mental retardation protein (FMRP). Loss of FMRP expression engenders enhanced activation of the mammalian target of rapamycin complex 1 (mTORC1) and extracellular signal-regulated kinase (ERK) signaling pathways in the brain of FXS patients and *Fmr1* knockout mice. The ERK pathway regulates mRNA translation largely via mitogen-activated protein kinase interacting kinases (MNK1/2)-dependent phosphorylation of eukaryotic initiation factor 4E (eIF4E), a cap binding protein that is critical for initiation of translation. Consistent with increased ERK activity, eIF4E phosphorylation is elevated in the brain of FXS patients and *Fmr1* knockout mice. The FXS mouse model recapitulates many core behavioral and morphological abnormalities of FXS patients such as social interaction deficits, repetitive behavior, dendritic spine dysmorphogenesis, and macroorchidism. In previous studies, downregulation of ERK and mTOR pathways rescued several pathologies in *Fmr1* knockout mice. Metformin, the most widely used anti-type 2 diabetic drug, represses the ERK and mTOR pathways, promotes lifespan, and protects against certain types of cancer and inflammation. In this study, we treated *Fmr1*$^{-/y}$ mice chronically with metformin. *Fmr1*$^{-/y}$ mice are impaired in the preference for social novelty part of the three-chamber social interaction task where they do not show a preference for the novel mouse. Meformin treatment corrected this impairment, where treated *Fmr1*$^{-/y}$ mice showed preference for the novel mouse similar as vehicle treated wild type mice. Increased grooming is a repetitive behavior observed in *Fmr1*$^{-/y}$ mice and metformin treatment decreased grooming comparable to wild type animals. Furthermore, metformin treatment rescued the excessive long-term depression (LTD), dendritic spine abnormalities and altered excitatory synaptic transmission in *Fmr1*$^{-/y}$ mice to the levels of vehicle treated wild type mice. Treatment with metformin also reduced the testicular weight in *Fmr1*$^{-/y}$ mice, but did not reach a weight of vehicle treated wild type mice. Using western blot, we showed that rescue of behavioral and morphological phenotypes in the *Fmr1*$^{-/y}$ mice after metformin treatment is due to selective normalization of ERK signaling pathway and consequently reduction of phospho-eIF4E, which is implicated in FXS. Together, metformin might be a novel therapeutic approach to restore specific behavioral and morphological aspects of FXS.

Title: Lovastatin treatment early in life prevents development of cognitive deficits in a rat model of Fragile X Syndrome

Authors: *A. ASIMINAS[1,2], S. M. TILL[2,3], E. K. OSTERWEIL[3,2,4], M. F. BEAR[4], S. CHATTARJI[5,6], D. J. A. WYLLIE[2,3,5], P. C. KIND[2,3,5], E. R. WOOD[1,2];

Inst., MIT, Cambridge, MA; [5]Ctr. for Brain Develop. and Repair, Bangalore, India; [6]Natl. Ctr. for Biol. Sci., Bangalore, India

Abstract: Fragile X syndrome, is the leading inherited cause of intellectual disability and autism, affecting hundreds of thousands of people worldwide. While several pharmaceutical interventions have been shown to rescue pathophysiology associated with genetic deletion of FMRP in mice, little is known about whether cognitive deficits can be prevented. Furthermore, it is not known whether benefits of early drug treatment are permanent or require ongoing treatment. This study directly examines whether deficits in associative, “episodic-like” memory can be prevented in a rat model of FXS and whether any benefits are dependent on ongoing treatment. In this study we focused on the effects of lovastatin on cognitive deficits associated with genetic deletion of FMRP, since Osterweil et al (2013) showed that lovastatin can indirectly reduce the exacerbated ERK signalling in *Fmr1* KO mice as well as reverse cellular and behavioural deficits associated with the syndrome. LEH rats (n=24 WT, n=24 KO) were fed either a control chow or a “lovachow” (100mg/kg lovastatin-containing diet) between 29 and 64

days old, and tested in 4 spontaneous exploration tasks: object recognition (OR), object-context (OC), object-place (OP), and object-place-context (OPC) recognition. KO rats receiving control chow showed performance consistent with our previous results - i.e. KO rats were delayed in ability to discriminate OP associations, and unable to discriminate OPC associations throughout the experiment (Asiminas et al, SfN 2014. Poster 669.15). However, lovastatin-treated KO rats demonstrated a developmental profile of associative memory indistinguishable from that of WT animals, while WT animals receiving lovachow showed a normal developmental trajectory. We next tested whether the enhanced performance in lovastatin-treated KO rats required ongoing lovastatin application, or whether the beneficial effects of this treatment were maintained into adulthood after lovastatin application had ended. At P64, lovachow was replaced with standard laboratory chow and the animals were tested 1 and 3 months later. Surprisingly, lovastatin treated *Fmr1* KO animals maintained the ability to perform the OPC task even at 5 months of age, whereas *Fmr1* KO animals on control chow showed no improvement with age. Our results show that not only can lovastatin treatment prevent the emergence of cognitive deficits associated with Fragile X Syndrome but also that lovastatin (and perhaps pharmaceutical interventions more generally) may prevent the developmental deficits in neuronal circuit formation which can be maintained into adulthood.

Title: Modulation of behavioral inhibition in attention deficit hyperactivity disorder

Authors: ***J. REN**[1,3], A. PANAMENO[4], L. M. HIRSHBERG[2,5], L. M. OBERMAN[2,3]; [1]Psychiatry and Human Behaviors, Brown Univ., Riverside, RI; [2]Psychiatry and Human Behaviors, Brown Univ., Providence, RI; [3]Neuroplasticity and Autism Spectrum Disorder Program, [4]Bradley Hosptal, Riverside, RI; [5]The NeuroDevelopment Ctr., Providence, RI

Abstract: Attention Deficit Hyperactivity Disorder (ADHD) is a prevalent child psychiatric disorder characterized by deficits in behavioral inhibition. One paradigm commonly used to evaluate behavioral inhibition is the stop signal task (SST). A cortical region implicated in this

task is the right inferior frontal gyrus (rIFG). Therefore, modulating the neural responses of the rIFG may lead to improvements in behavioral inhibition in individuals with ADHD.
The current study investigated this question using noninvasive brain stimulation. We applied anodal, cathodal, and sham stimulation over rIFG using transcranial direct current stimulation (tDCS) that provides a weak direct current to the scalp and examined the effects of stimulation on ADHD participants' performance on the SST as well as electroencephalography (EEG) and event related potentials (ERPs) related to behavioral inhibition. 15 adolescents aged 13-17 have been tested thus far. Participation consisted of 4 visits: a baseline and 3 stimulation visits (anodal, cathodal and sham). During each stimulation visit, participants received 15 minutes of tDCS over rIFG. Immediately after that, they completed the SST. During the SST, left or right arrows were presented on each trial and participants responded with a button press as quickly as possible. However, an auditory stop signal was presented in some trials instructing the participant to stop their responses. ERPs were recorded during the SST. A 5 minute resting EEG was recorded immediately prior to stimulation as well as following the SST.
Here we report interim analyses. Behavioral results showed a significant effect for stimulation on the participants ability to stop their responses ($F(3,12)=6.067$, $P=0.009$). Specifically, cathodal compared to sham stimulation lead to significant improvements (($F=4.819$, $P=0.045$)). Preliminary results for the resting EEG also suggested an important trend for reduced θ frequency and θ/β ratio at rIFG after stimulation for both anodal and cathodal conditions, suggesting that tDCS over rIFG may modulate neural correlates for behavioral inhibition. Data continues to be collected and further analyses will be conducted on the final dataset.
This is the first study to investigate the effects of a single session of tDCS over rIFG targeting behavioral inhibition in adolescents with ADHD. Current data indicate that tDCS to rIFG leads to transient improvements in behavioral inhibition and potentially the functioning of related neural circuitry. Such findings suggest that tDCS may be used as a novel clinical intervention for ADHD. Our findings also have significance in understanding the brain mechanism for inhibitory processes.

Title: Children with DCD (development coordination disorder) have a normal rate of learning of Active Video Games both in a variable and repetitive learning protocol.

Authors: B. C. M. SMITS-ENGELSMAN[1], E. BONNEY[1,2], L. D. JELSMA[3], G. FERGUSON[1], *J. E. DUYSENS[4];
[1]Dept. of Hlth. and Rehabil. Sci., Univ. of Cape Town, Cape Town, South Africa; [2]Dept. of Physical Therapy, Univ. of Ghana, Accra, Ghana; [3]Developmental and Clin. Neuropsychology, Univ. of Groningen, Groningen, Netherlands; [4]Dept of Kinesiology (faber), K.U.Leuven, Belgium

Abstract: Introduction: Children with DCD (development coordination disorder) have difficulty in learning motor skills, yet under particular conditions they learn at the same rate as TDC (typically developing children (Smits-Engelsman et al. 2015). The latter was demonstrated using repetitive learning. Since there are indications that variable learning is superior to repetitive training (Schmidt 1975) the question arises whether variable practice leads to better learning and transfer than repetitive training. We examined if the rate of learning was different in these two training protocols. Moreover we tested if the transfer effect was different between protocols. Finally the question was asked if children with development coordination disorder (DCD) would benefit more from one of the protocols. Material and Methods: Some 111 children aged 6-10 (M 8.0 =, SD=1.0) with no active computer gaming experience were randomly divided in two groups. The first group (Variable, n=55) followed a training program with a variable protocol ("Variable", 10 different games) while the second group ("Same", n=56) followed a repetitive practice protocol (same game in every session). Half the participants in each group met the criteria for DCD. All subjects experienced 5 weeks of training two times per week, for 20 min. Both protocols aimed at learning dynamic balance and agility skills. Changes in outcome in a test game and in motor test scores were examined pre- and post-training. In addition their rate of learning was calculated over the 5 weeks of intervention. Results: ANOVA repeated measures indicated that, after the training, children submitted to the "Same" protocol outscored the ones in the "Variable" protocol on the test game (Protocol x Training). Importantly, there was no interaction effect between protocol (Same and Variable) and participant groups (TD and DCD). There was a significant transfer effect to the other balance tasks (both virtual and real life tasks) but transfer was not better for one of the protocols. Conclusions: By playing active computer games the motor performance,, especially balance, gets better, both in typically developing children and in children with poorer motor coordination. Our results confirm that there is transfer of training from video games to untrained tasks. The results do not confirm the generally held belief that DCD children are less able to learn. Title: Consequences of excessive sensory stimulation during development on addiction, impulsivity and attention

Authors: *S. RAVINDER, S. GADIWALLA, D. CHRISTAKIS, S. FERGUSON, J.-M. RAMIREZ;
Seattle Children's Res. Inst., Seattle, WA

Abstract: Early life experiences exert long-lasting effects on neural function, which can have a deep impact on behavior and vulnerability to developing neuropsychiatric illnesses such as Attention deficit hyperactivity disorder (ADHD). Most ADHD research has focused on understanding genetic causes, but there remains a large role for environmental factors in the etiology of this disease. We have developed a rodent model of "excessive sensory stimulation (ESS)" whereby mice are exposed to audio-visual stimuli for 6 h/day, from P10-P52 (Christakis et al., Sci Rep., 2012). When subsequently tested, ESS mice demonstrate numerous behavioral outcomes that are reminiscent of the clinical symptoms of ADHD (inattentiveness, impulsivity, hyperactivity). Compared to controls, ESS mice show poorer short-term memory, impaired learning and attention in memory tests; hyperactivity and increased risk-taking in multiple anxiety tests. ADHD is known to be highly comorbid with substance abuse. Here we investigated the relationship between ESS and vulnerability to drugs of abuse in adulthood. We found that ESS mice displayed locomotor hyperactivity that develops over time but showed blunted psychomotor sensitization to cocaine when compared to controls. Interestingly, ESS mice develop a stronger conditioned place preference for cocaine compared to controls, suggesting that they may have a higher addiction liability. To further characterize the behavioral impact of ESS, we are currently examining the effects of ESS in the 5-choice serial reaction time test and the delay-discounting test, both of which are well-established models for testing impulsivity and attention. Our initial data from the delay discounting test suggests that ESS mice make more impulsive choices than controls. At the cellular level, our experiments show that ESS leads to an increase in miniature excitatory postsynaptic currents in the nucleus accumbens, amygdala and medial prefrontal cortex (mPFC). We are currently pursuing experiments to further characterize these cellular effects. Many studies have shown that changes in the frontal cortex may underlie impulsivity and attention in animal models and ADHD symptoms in humans. In future experiments, we plan to modulate *in-vivo* activity in the mPFC of ESS and control mice to

explore the role of this brain region in ESS induced changes in impulsivity and attention. Our study has important implications in today's increasingly complex technological age where children face a tremendous amount of sensory stimulation that could interact with genetic predispositions to produce detrimental effects on behavior and brain function.

Title: Attention training in children with sensory processing dysfunction.

Authors: *A. AITKEN, J. A. ANGUERA, A. D. ANTOVICH, C. E. ROLLE, S. S. DESAI, E. J. MARCO;
UCSF, San Francisco, CA

Abstract: Background:
Children with Sensory Processing Dysfunction (SPD) have profound behavioral issues stemming from their atypical behavioral responses to incoming sensory stimuli and, frequently, attention-based deficiencies. It has been estimated that 40% of children with SPD will meet diagnostic criteria for Attention Deficit and Hyperactivity Disorder (ADHD). However, there is uncertainty regarding the most effective treatment option at an individual level, especially when considering non-pharmaceutical approaches.
Objectives:
In the current study, we present behavioral and neuroimaging work aimed to determine if training with an interactive digital game-like tool (EVO) would enhance attention in children with SPD relative to age-matched controls.
Methods:
We recruited 19 typically developing children (TDC), 17 children with SPD and inattentive traits (SPD_{+IA}) and 13 children with SPD without inattentive traits (SPD_{-IA}) through the UCSF SNAP

Center. All children played EVO over a one-month period. Pre and post training, we assessed response time (RT) and response time variability (RTV) in the Test of Variables of Attention (TOVA), a Go/NoGo assessment, EVO assessment, a neurophysiological measure of cognitive control (Midline Frontal Theta using EEG), and a parent report measure of inattention (Vanderbilt).

Results:

Using an linear mixed model analysis, we found a significant main effect by session for TOVA RT ($F(1,56)= 13.6$, $p= .001$) and RTV ($F(1,56)= 6.0$, $p= .02$), Go/NoGo RT ($F(1,54)= 26.5$, $p<.001$,), and EVO RT ($F(1,52)= 103.1$, $p \leq .001$) and RTV ($F(1,52)= 45.3$, $p\leq .001$). Midline frontal theta (MFT) power during Go/NoGo play showed a significant group x visit interaction ($F(2,47)= 5.9$, $p= .007$), with post-hoc tests revealing that only the SPD_{+IA} group showed enhanced MFT power following training ($p\leq .001$). The Vanderbilt parent report also showed a significant group x session interaction ($F(2,61)= 9.8$, $p\leq .001$), with post-hoc tests revealing that only the SPD_{+IA} group showed reduced inattention ($p\leq .001$), with these improvements persisting for 9 months. Critically, we observed a significant relationship between increased MFT power and decreased parent reported inattention via the Vanderbilt ($r=.41$, $p=.017$).

Conclusions:

These findings support the benefit of a specific targeted attention-based intervention for children with SPD and symptoms of ADHD, with evidence of brain plasticity and impact on real world function. These outcomes also highlight the importance of having a detailed cognitive assessment of attention in children with neurodevelopmental conditions to properly personalize subsequent treatment approaches.

Title: C-terminal RELN deletion disrupts an interaction with VLDLR causing abnormal cerebral cortex and hippocampus development

Authors: *S. HA[1,3], P. P. TRIPATHI[2], R. F. HEVNER[2,3], D. R. BEIER[1,3];
[1]Developmental Biol. and Regenerative Med., [2]Ctr. for Integrative Brain Res., Seattle Children's Res. Inst., Seattle, WA; [3]Univ. of Washington Med. Sch., Seattle, WA

Abstract: We discovered a hypomorphic *reelin* (*Reln*) mutant with abnormal cortical lamination and no cerebellar hypoplasia. This mutant, $Reln^{CTRdel}$, carries a splice-site mutation that truncates the C-terminal region (CTR) domain and displays remarkably distinct phenotypes from *reeler*. The mutant does not have an inverted cortex, but cortical neurons overmigrate and invade the marginal zone, which is very similar to a phenotype seen in the cerebral cortex of $Vldlr^{null}$ mice. Moreover, the dentate gyrus shows a novel phenotype; the infrapyramidal blade is absent, while the suprapyramidal blade is present and laminated. Genetic epistasis analysis showed that $Reln^{CTRdel}/Apoer2^{null}$ double homozygotes have phenotypes akin to *reeler*, while $Reln^{CTRdel}/Vldlr^{null}$ mice do not. Given that the receptor double-knockout mice resemble *reeler,* we infer that $Reln^{CTRdel}/Apoer2^{null}$ double homozygotes have both receptor pathways disrupted. Therefore, these results suggest that CTR-truncation disrupts an interaction with VLDLR, while the APOER2 signaling pathway remains active, which accounts for the hypomorphic phenotype in $Reln^{CTRdel}$ mice.

Title: A possible novel mode of action for Dab1 in modulation of neuronal migration of neocortical neurons

Authors: *S. KIKKAWA, T. NAMIKAWA, T. TERASHIMA;
Kobe Univ. Grad. Sch. of Med., Kobe-Shi, Japan

Abstract: Neurons in the developing mammalian neocortex form a laminar structure in an ﾒinside-outﾓ manner. This layered structure is established by coordinated neuronal migration regulated by several signaling cascades, including the Reelin-Disabled-1 (Dab1) pathway. Dab1 comprises a N-terminal (Nt) region, which contains the phosphotyrosine-binding (PTB) domain followed by a cluster of five tyrosines, and a C-terminal (Ct) region with unknown functions. We

have previously investigated the effects of various truncated forms of Dab1 on the morphology of transfected cells and postulated a possible intramolecular regulatory mechanism between the Nt and Ct domains within Dab1. To explore this interaction *in vivo*, we expressed various Nt and Ct fragments in migrating neocortical neurons using an *in utero* electroporation technique and analyzed radial migration of the transfected neurons. When transfected with the Dab1 Nt fragment along with a GFP tracer plasmid at E14.5, most neurons, which normally comprise layer II/III, ceased migration and accumulated ectopically in the intermediate zone. The site of accumulation and the morphology of accumulating cells suggest that these cells failed to switch from multipolar migration to bipolar locomotion. This premature migration arrest occurred irrelevantly to phosphorylation in the tyrosine cluster within the Dab1 Nt fragment and required neither endogenous Reelin nor Dab1. When the Nt fragment was cotransfected with its complementary Ct fragment, the migration arrest was partially rescued to the extent comparable to the case of full-length Dab1 transfection. Intriguingly, overexpression of either constitutively active Rap1 or a Rap1 guanine nucleotide exchange factor, RapGEF2, also rescued the Nt-fragment-mediated migration arrest. Taken together, these results suggest that the Dab1 Ct domain interacts with the Nt counterpart so that it modulates the activity of the Nt domain, and also that Dab1 may act in the RapGEF2-Rap1 pathway upon multipolar-bipolar transition of migrating neocortical neurons.

Title: Cdk12 regulates neurogenesis and late-born neuronal migration in the developing cerebral cortex

Authors: ***M.-J. FANN**, H.-R. CHEN, H.-C. JUAN, Y.-H. WONG, J.-W. TSAI;
Natl. Yang-Ming Univ., Taipei, Taiwan

Abstract: The DNA damage response (DDR) pathways are critical to ensure that replication stress and other types of DNA lesion do not perturb production of neural cells during development. Neural progenitor cells are particularly sensitive to DNA damage and their relative susceptibility may vary depending on the stage of development. Defective DDR pathways are often associated with neural developmental abnormality. Cdk12 maintains genomic stability by regulating expression of DDR genes. To define its role during neural development *in vivo*, we conditionally targeted *Cdk12* using a Nestin-Cre mouse line. Nestin-Cdk12-cKO mice do not survive beyond postnatal day 0 (P0) and exhibit microcephaly. Results from cresyl violet-stained brain sections of Nestin-Cdk12-cKO at P0 show reduced thickness of cortical plate layers in cerebral cortex, and aberrant anterior commissure and corpus callosum. We show that neural progenitor cells of mutant mice accumulate at G2 and M phase, and have lower expression of DDR genes, more DNA double-strand breaks and increased apoptosis. Furthermore, results from birthdating experiments show that Cdk12 involves not only in neurogenesis of neural progenitor cells, but also in neuronal migration of late-born neurons in the developing cerebral cortex. Although 6-cortical layer organization is preserved, misaligning of layers IV–II neurons marked with CUX1 expression is observed. Results from DiI tracing also show a loss of the corpus callosum that is composed of axons of callosal projection neurons located in layer III/II. To further investigate effects of Cdk12 on neuronal migration without its confounding effect on neurogenesis, we investigated the $Cdk12^{fx/fx}$ mice that were electroporated *in utero* with Cre-expression plasmid between embryonic day 14 to 16. Migrating mutant neurons are stagnant within the intermediate zone and fail to adopt a bipolar morphology. As Cdk12 is required for Cdk5 expression, we demonstrate that overexpression of Cdk5 brings about a partial restoration of the neurons reaching layers IV-II in the mutant mice. Thus, Cdk12 is crucial for the repair of DNA damage during the proliferation of neural progenitor cells and is also central to the proper migration of late-arising neurons.

Abstract: Epileptic encephalopathies (EEs) are neurodevelopmental diseases characterized by early-onset epilepsy with cognitive deficits. The etiology of these disorders remains uncertain in a large proportion of patients. However, recent data suggest that defects in the development of inhibitory interneurons (INs) may perturb the connectivity and aberrantly enhance the excitability of cortical circuits, underlying a subset of genetically determined seizure disorders. Mutations in the *TRIO* gene have been recently identified using whole-exome sequencing in patients with EE or isolated intellectual deficiency by our lab and others. *Trio* encodes a guanine nucleotide exchange factor (GEF) that interacts with multiple Rho GTPases, such as Rac1, RhoG and RhoA, implicated in fundamental aspects of neuronal development, including cell cycle regulation, neurite outgrowth, nucleokinesis and caudal neurite retraction. *Trio* has been shown to regulate the axonal guidance, dendritic development and lamination of hippocampal pyramidal cells. However, the roles of *Trio* in the development INs are unknown. Considering the proposed involvement of *Trio* in neuronal development, and given the critical role of INs in preventing seizure disorders, we hypothesized that *Trio* might be an important regulator of the development and connectivity of cortical INs. To investigate this hypothesis, we performed a targeted repression of the *Trio* gene by *ex vivo* electroporation of a *Dlx5/6::shRNA-tdTomato* plasmid in organotypic cultures of e13.5 mice embryonic cortex. Using time-lapse confocal imaging, we evaluated the morphology and dynamics of migrating INs. We also investigated the migration dynamics of genetically modified INs from MGE-explants plated on a cortical feeder layer. Finally, we genetically repressed *Trio* in post-natal cortical parvalbumin-positive (PV) INs by biolystic transfection of a 10kb-GAD67::shRNA in postanatal cortical organotypic cultures. We assessed the morphological development of PV-INs and the extent of their innervation of cortical pyramidal cells. Our preliminary results show that the repression of *Trio* in migrating cortical INs significantly alters their morphology and impairs their migration. This data suggests that *TRIO*-associated EE might be, in part, due to a defect in the early development of cortical INs.

Title: Dopamine D1 receptor activation and neuronal migration

Authors: ***M. M. MARTIN**[1,2], D. M. MCCARTHY[2], C. METIN[3], P. G. BHIDE[2];
[1]Biomed. Sci., Florida State Univ., Tallahassee, FL; [2]Ctr. for Brain Repair at Florida State Univ., Tallahassee, FL; [3]Inserm - Inst. du Fer à Moulin, Paris, France

Abstract: Neurotransmitters play unique growth-promoting roles in the developing nervous system, which are distinct from their canonical role at the synapse in the mature nervous system. We have shown that the neurotransmitter dopamine (DA) and its receptors not only appear in the fetal brain during early development but also play critical roles in developmental phenomena such as cell proliferation, neuronal migration, differentiation and circuit formation. Perturbation of these developmental events is believed to be associated with a number of neurological and psychiatric disorders with developmental onset. Many of these developmental disorders are also associated with impairment of inhibitory GABA circuits. GABA neurons originate in the dopamine-rich medial ganglionic eminence (MGE) of the embryonic basal forebrain and migrate to regions of the dorsal forebrain. These migrating GABA neurons express dopamine receptors. Therefore, we hypothesized that dopamine receptor activation influences migration of the GABA neurons. Using live cell imaging techniques, we examined the migratory behavior of these GABA neurons following application of the DA type 1 receptor (D1R) agonist SKF 81297. We used a co-culture system in which MGE explants were plated on dissociated cortical neurons; both obtained from embryonic day 13 mice. Following 24 hours in culture, the D1R agonist (1 μM) was applied and live cell imaging was performed over a 7 hr period. We found the migration velocity of treated GABA neurons to be significantly decreased by 28% compared to those treated with a vehicle control. Migrating GABA neurons typically display a saltatory behavior characterized by the alternation between a nuclear jump-like movement and a nuclear resting phase. We found that D1R agonist application significantly increased the average time that GABA neurons spent in the resting phase by 35%. Moreover, D1R agonist application significantly decreased the frequency of medium jumps (characterized by an instantaneous migration velocity between 1.2 and 2.4 μm/min) by 30% and the frequency of large jumps (characterized by an instantaneous migration velocity greater than 2.4 μm/min) by 36%. Collectively, these results demonstrate that D1R activation can alter the migratory behavior of GABA neurons during early brain development suggesting a role for impaired D1R activity in the etiology of developmental disorders associated with dopamine imbalance.

Title: Polysialic acid synthesis by ST8SIA2 is essential for cortical interneuron development

Authors: *U. E. DIEDERICHS[1], C. ROSSDAM[1], T. KRÖCHER[1], I. RÖCKLE[1], N. KESSARIS[2], Y. YANAGAWA[3], B. WEINHOLD[1], H. HILDEBRANDT[1];

Abstract: The neural cell adhesion molecule NCAM and its modification with polysialic acid (polySia, PSA-NCAM) are major determinants of brain development. Polysialylation of NCAM is implemented by the polysialyltransferases (polySTs) ST8SIA2 and ST8SIA4. Dysregulation of polySia-NCAM and variation in *ST8SIA2* have been implicated in psychiatric disorders such as schizophrenia. Previously, we described reduced interneuron densities in the prefrontal cortex of ST8SIA2- or ST8SIA4-negative mice and demonstrated that acute enzymatic removal of polySia in organotypic slice cultures causes impaired entry of interneurons into the embryonic cortex as well as slower migration within the cortical environment (Kröcher et al. 2014, Development 141:3022). However, the spatiotemporal impact of the two polySTs on the migration process remained unresolved. Here we characterize altered interneuron migration by live cell imaging of ST8SIA2-deficient embryos. To distinguish between a cell-autonomous effect of polySia produced by ST8SIA2 in migratory interneurons and its role in the cortical environment, the migration of GFP-labelled interneurons from the medial ganglionic eminence (MGE) into the cortex was studied in MGE- and cortex-explants obtained from wildtype or ST8SIA2-deficient embryos that were co-cultured in different combinations. A potential link between cell-autonomously altered polySia and reduced cortical interneuron densities was assessed by analyzing mice with a conditional knockout of *St8sia2* either in MGE-derived interneurons (*Lhx6-Cre*) or in the cortex (*Emx1-Cre*). The results point towards a differential impact of polySia produced by ST8SIA2 in migratory interneurons and in their cortical environment on the migration process as well as on the establishment of interneuron densities in the mouse cortex.

Title: Dynamin-related protein 1 controls the migration and neuronal differentiation of subventricular zone-derived neural progenitor cells

Authors: *H. KIM[1], M. SHAKER[1], B. CHO[2], H. CHO[1], H. KIM[1], J. KIM[1], W. SUN[1]; [1]Korea Univ., Seoul, Korea, Republic of; [2]DGIST, Daegu, Korea, Republic of

Abstract: Mitochondria mediate many cellular functions required for cell survival and maintenance, as they play a prominent role in energy production and calcium homeostasis. The organelles are scattered throughout the cytoplasm, but their distribution can be altered in response to local energy demands, such as cell division and neuronal maturation. Mitochondrial distribution is closely associated with mitochondrial fission, and blocking dynamin-related protein 1 (Drp1) activity often results in mitochondrial elongation and clustering. In this study, we observed that mitochondria were preferentially localized at the leading process of migratory adult neural stem cells (aNSCs), whereas neuronal differentiating cells transiently exhibited perinuclear condensation of mitochondria. Inhibiting Drp1 activity altered the morphology of migrating cell from elongated to round, while the polarized mitochondrial distribution was maintained. With these changes, aNSCs failed to migrate and differentiate. Because blocking Drp1 activity also impaired the mitochondrial membrane potential, we tested whether supplementing with L-carnitine, a compound that restores mitochondrial membrane potential and ATP synthesis, could rescue the defects induced by Drp1 inhibition. Interestingly, L-carnitine fully restored the impaired cell morphology, migration and differentiation in aNSCs. These results suggest that Drp1 is important for regulating mitochondria to produce ATP for proper migration and differentiation, and supplementing with ATP can restore the defects induced by Drp1 suppression.

Title: Insulin growth factor 1 control of subventricular zone progenitor migration

Authors: ***M. DUCKER**[1], B. HASSAN[2], F. SZELE[1];
[1]Dept. of Physiol. and Genet., [2]Sir William Dunn Sch. of Pathology, Univ. of Oxford, Oxford, United Kingdom

Abstract: The subventricular zone (SVZ) of the lateral ventricles is one of the two major neurogenic niches in the adult mammalian brain. SVZ neural stem cells proliferate and generate thousands of highly motile neuroblasts daily that migrate to the olfactory bulb or, under pathological conditions, to the site of injury. Evidence from the literature supports the hypothesis that the Insulin-like Growth Factor (IGF) system orchestrates both the proliferation and migration of SVZ progenitors. However, it is unknown how the balance between proliferation and migration is achieved.
We employed in vitro explant assays and two photon time lapse microscopy of neuroblasts migrating in live brain slices to study the role of IGF signalling in the SVZ. This is combined with fluorescence resonance energy transfer (FRET) biosensors to correlate IGF stimulation of key kinase pathways with the dynamics of proliferation and migration to examine the effects of IGF signalling on SVZ migration.
Stimulation with recombinant IGF1 increased migration of neuroblasts from SVZ explants. This effect was blocked by small molecule inhibitors of the IGF1R and the PI3K and MAPK pathways. Co-treatment with the Insulin-like growth factor binding protein 5 (IGFBP5) potentiated the promigratory effect of IGF1, while treatment with IGF2 failed to elicit significant increases in migration. Interestingly in these assays epidermal growth factor (EGF) induced migration of cells with non-neuroblast morphology. We are currently working to fully characterise the expression of the different components of the IGF system on the different cell types in the SVZ. Targeted manipulation of the IGF system may offer therapeutic potential for directed neuroblast migration in neuroregeneration.

Title: *In vivo* two-photon imaging of cell migration in embryos reveals a differential effect of ketamine application

Authors: ***M. YURYEV**[1], L. ANDRIICHUK[1], V. JOKINEN[2], C. RIVERA[1,3,4];
[1]Univ. of Helsinki, Helsinki, Finland; [2]Aalto Univ., Espoo, Finland; [3]Inst. de Neurobiologie de la Méditerranée, Marseille, France; [4]Aix-Marseille Univ., Marseille, France

Abstract: Correct neuronal migration is an essential part of the process of cortical development. Alterations in the mechanism regulating speed of migration may have profound consequences in the incorrect structure of cortical networks. Individual cellular populations mature at various rates and might respond to different extracellular cues. The varying effects might stem partly from differential expression of glutamatergic and GABAergic receptors. However, the functionality of these receptors in different cellular populations remains unclear. To date, the physiological behaviour of migrating neurons has been mainly studied in *ex vivo* models such as neuronal cultures and brain slices. These reduced systems do not necessarily reflect the complexity of molecular and electrical signalling of the brain *in vivo*. In the present work we took advantage of a recently developed method of *in vivo* two-photon imaging of live mouse embryos connected to the mother at gestational day E14. We used Sox2-GFP reporter mouse to track the migration of undifferentiated cells. Then we exploited the ability of Fluo4-AM dye to selectively label differentiated neurons after *in vivo* intraventricular dye loading. With this approach we study the differences in migration of this cell population in comparison to Sox2-positive cells. We injected ketamine intraventricularly in order to block NMDA receptors. This

treatment induced reduction in the migration speed in both populations. However, in contrast to Sox2-positive cells, ketamine application had significantly stronger effects in differentiated neurons. The results imply the involvement of NMDA receptors selective regulation of migrating neurons *in vivo*. In addition, this method could be used to estimate the effects of maternal exposure to chemicals on acute cellular migration and and thus serve as a drug screening platform.

Title: Understanding neurovascular endothelial cell migration using *In vitro* three dimensional models

Authors: M. BOUTIN[1], J. SEVETSON[2], L. KRAMER[3], *D. HOFFMAN-KIM[4];
[1]BME, MPPB, [2]Neurosci., [3]MPPB, [4]MPPB, BME, BIBS, Brown Univ., Providence, RI

Abstract: The neurovascular unit is a complex environment composed of diverse neural cell types and basement membrane proteins, which coordinate to deliver oxygen and nutrients to the brain, and to protect the brain from toxins and metabolic fluctuations in the blood stream. Pathological changes to neural vasculature occur in many disease states, such as cancer, stroke, and neurodegeneration. Understanding the cellular dynamics behind pathological vascular changes is an imperative step towards the development of effective therapeutics. To this end, our lab has characterized the formation and dynamics of *in vitro* neurovascular capillary-like networks. *The goal of the current study was to characterize the response of capillary-like networks to the introduction of different cell types, to mimic potential in vivo disease states.* We previously described a primary cortical spheroid model that enables the *in vitro* study of *in vivo*-relevant characteristics, such as cell density, cell composition complexity, neuronal electrophysiology, tissue stiffness, and dimensionality. Importantly, cortical endothelial cells spontaneously assemble into capillary-like network structures within cortical spheroids. In the current study, a coculture method was used to study the fusion of a cortical spheroid and a

spheroid composed of a different cell type. The fibroblast cell line NIH3T3 and the endothelial polyoma cell line bEnd.3 were selected to create candidate coculture spheroids. After coculture of cortical spheroids and NIH3T3 spheroids, the two discrete spheroids fused to form one microtissue, and capillary-like networks were observed within NIH3T3 regions of fused microtissues. After coculture of cortical spheroids and bEnd.3 spheroids, capillary-like structures were observed at the interface between the fused spheroids. These results demonstrate the complex differential responses of cortical capillary-like networks to introduced cell types. Future work aims to investigate the interaction of capillary-like networks with different introduced cell types and to identify the driving factors of endothelial cell migration, with the goal of informing vascular changes in disease states.

Abstract: Derived from the neural crest, Schwann cells are the nonmotile, myelinating glia of the peripheral nervous system. Although the transitional stages of the embryonic Schwann cell have been characterized, the guidance signals have yet to be determined. Since neuroregulin-1 (NRG1) is essential for survival and generation of Schwann cell development, we decided to include neurotrophins also known to be present in the developing embryo and important for the survival of glia in the peripheral nervous system (PNS). More specifically, we want to know if NRG1, nerve growth factor (NGF) and glial derived neurotrophic factor (GDNF) are chemoattractants and/or chemokinetic molecules for Schwann cells. We implemented a

chemoattraction assay with live imaging in addition to chemokinetic assays to measure motility. Our findings suggest NRG1 and NGF are strong chemoattractants for Schwann cells while NRG1 and GDNF are chemokinetic molecules for their motility.

Inst. for Physiological Sci., Okazaki, Japan

Abstract: During cerebral cortical development, neurons and glia are produced directly or indirectly from neural stem cells in the ventricular zone and migrate to their final destinations. Although the migratory process and its molecular mechanisms of cortical neurons are well described, those of glial progenitors are largely unknown. During our observations of the cells migrating from the cortical ventricular zone, we have noticed that some cells moved in a very unique manner that had not been previously described: these cells moved very rapidly and almost randomly within the intermediate zone and the cortical plate and frequently divided. We named this migration “erratic migration”. The lineage analyses of them both in vitro and in vivo revealed that they were astrocyte progenitors destined for cortical gray matter. Interestingly, these cells frequently migrated along blood vessels, which are running radially in the cortical plate during the embryonic and perinatal stages, and reached superficial layers of the cortical plate. The molecular mechanism of the blood vessel-guided migration will be discussed.

Title: EphA4 signaling controls neuroblast migration and astrocyte organization in the rostral migratory stream

Authors: ***J. C. CONOVER**[1], K. L. TODD[2], K. L. BAKER[2], M. EASTMAN[2], F. KOLLING, 4th[2], C. E. NELSON[3];

Abstract: Newly generated neuroblasts from the subventricular zone (SVZ) migrate from the lateral ventricle through the anterior forebrain to their ultimate site of differentiation in the olfactory bulb. The migration pathway through the forebrain, the rostral migratory stream (RMS), consists of densely packed, tangentially oriented neuroblasts transiting through a meshwork of astrocytes. To support efficient and controlled migration of neuroblasts, the RMS needs to be tightly regulated, spatially restricted, and yet permissive. What regulates the dynamic interaction between migratory neuroblasts and the glial meshwork that makes up the RMS? We found that EphA4 tyrosine kinase receptor signaling is required to confine neuroblasts within the RMS and to organize the astroglial meshwork. Single cell analysis revealed that EphA4 and its ephrin partners are expressed in a complex mosaic pattern by subpopulations of neuroblasts and astrocytes within the RMS, implicating EphA4 signaling in both neuroblast-neuroblast and neuroblast-astrocyte interactions as crucial for regulating the dynamic interplay between neuroblast migration and controlled boundary maintenance supported by RMS astrocytes. In sum, our data supports a novel molecular mechanism involving EphA4 signaling that is necessary for controlling neuroblast migration in the RMS.

Title: Cytoskeletal dynamics during neuronal migration: Role of actin binding protein drebrin in GnRH neuronal movement

Authors: *Y. SHAN, S. WRAY;
NINDS, NIH, Bethesda, MD

Abstract: Gonadotropin-releasing hormone (GnRH) neurons are essential for reproductive maturation and function. In vertebrates, GnRH neurons migrate from the nasal pit into the brain during embryonic development. Numerous guidance molecules are involved in this process to ensure GnRH neurons reach their final destination, since disruption of migration can result in infertility. GnRH cell movement is regulated through cytoskeletal modification in response to these guidance cues. These cytoskeletal changes include rapid assembly/disassembly of actin filaments and microtubules, and extension of the leading process and growth cones. However, the exact mechanisms by which guidance cues 'talk' to the cytoskeleton of GnRH neurons remain unclear. Previous data in our lab indicated that 1) stromal cell-derived factor 1 (SDF-1) accelerates GnRH neuronal migration rate and 2) 'capturing' microtubule + ends to cortical actin in migrating GnRH neurons occurs via calcium dependent mechanisms. It is known that SDF-1 binds to CXCR4, a g-protein coupled receptor that can increase release of calcium from internal stores. Large numbers of actin/microtubule binding proteins regulate cytoskeletal dynamics during neuronal migration, including developmentally regulated brain protein (drebrin), which is thought to stabilize actin filaments. Drebrin has been shown to interact with microtubule end-binding proteins through cdk signaling pathways to regulate cytoskeletal dynamics and has been proposed to regulate Ca^{2+} influx through actin organizing. Thus drebrin is a candidate actin/microtubule binding protein that may link receptor signaling to cytoskeletal changes during neuronal migration. In the current study, we identified that drebrin is expressed along the actin cortex and growth cone of migrating GnRH neurons, but not in the olfactory/vomeronasal axons along which GnRH cells migrate. In migrating GnRH neurons, drebrin was also colocalized with the microtubule-associated protein double cortin (DCX), consistent with a role for drebrin guiding the microtubule bundles into the actin cortex. Functional assays have been performed using embryonic mouse nasal explants that maintain large numbers of primary GnRH neurons migrating in association with outgrowing olfactory axons. Inhibition of drebrin using the calcium

release activated channel (CRAC) inhibitor BTP2 decreased GnRH neuronal migration rate, consistent with drebrin being involved in the mechanism of cytoskeletal modification. Further work will focus on the interaction of the SDF-1 receptor, CXCR4, and drebrin during GnRH neuronal migration.

Title: Does GPR56 play a role in the developing GnRH/Olfactory system?

Authors: ***F. VILSON**[1], Y. SHAN[1], X. PIAO[2], S. WRAY[1];
[1]NIH, Bethesda, MD; [2]Div. of Newborn Med., Boston's Children's Hospital, Harvard Med. Sch., Boston, MA

Abstract: The Gonadotropin Releasing Hormone-1 neuron (GnRH-1) system controls reproductive maturation and function via the release of Follicle Stimulating Hormone (FSH) and Luteinizing Hormone (LH) from the pituitary gland. During embryonic development, GnRH neurons migrate into the forebrain from the nasal placode. The factors/signals that guide these cells into the forebrain are not fully understood. Microchip data obtained from single GnRH neurons maintained in nasal explants indicated a high level of transcripts for GPR56. GPR56 is a member of the adhesion class of the G protein coupled receptor superfamily. Previous reports indicate that mice with mutations in the GPR56 gene exhibit a lack of structural integrity of the cerebral cortex and over-migration of cortical neurons, moving beyond the pial basement layer. The present study examines whether GPR56 plays a role in GnRH neuronal migration. Single cell RT-PCR confirmed expression of GPR56 transcript in GnRH neurons during migration and immunocytochemistry showed a subpopulation of GnRH cells express the receptor. Examination of GPR56 KO mice is in progress to determine if the number and/or location of GnRH cells are perturbed.

Title: Distinct roles for the adhesion molecule Contactin2 in the development and function of neural circuits in zebrafish.

Authors: *S. GURUNG, A. CHANDRASEKHAR;
Div. of Biol. Sci., Columbia, MO

Abstract: Neuronal migration and axon guidance are critical developmental processes essential for the establishment of functional neural circuits. Following migration, neurons extend axons that navigate precisely to targets to generate neural networks controlling complex motor and cognitive functions. Migrating neurons as well as navigating axons express a variety of cell surface molecules that to interact with the environment enroute to their destinations. Contactin2 (Cntn2)/Transiently-expressed Glycoprotein 1 (Tag1), a glycosylphosphatidylinositol anchored cell adhesion molecule of the immunoglobulin superfamily, is expressed in specific neuronal types during vertebrate nervous system development. Our previous studies using morpholinos suggested that *cntn2* is necessary for the migration of facial branchiomotor (FBM) neurons, a subset of branchimotor neurons that arise in rhombomere 4 of the hindbrain and migrate caudally to rhombomere 6, and that it genetically interacts with the planar cell polarity gene *vangl2* during FBM neuron migration. To validate these data, we generated loss-of-function mutations in *cntn2* using CRISPR/Cas9, and identified three alleles including two frameshift mutations generating premature stop codons (*zou20* and *zou22*) that exhibited identical phenotypes. *cntn2* expression was greatly reduced in $cntn2^{zou20}$ *and* $cntn2^{zou22}$ homozygotes, and Cntn2 protein was undetectable in both cases, suggesting these identified alleles are null. In contrast to the morphant phenotype, zygotic and maternal-zygotic (MZ) $cntn2^{-/-}$ mutants exhibited normal FBM neuron migration, suggesting either that the morphant phenotype is due to off-target effects or that there is genetic compensation from related genes in MZ mutants. Consistent with the latter, FBM neurons failed to migrate caudally in a significant fraction of $cntn2^{+/-}$; $vangl2^{+/-}$ embryos obtained from $cntn2^{-/-}$ mothers, supporting the genetic interaction observed using morpholinos. Previous studies showed that morpholino-mediated *cntn2* knockdown generated defasiculation defects in midbrain nucMLF and spinal cord Rohon-Beard (RB) axons. However, MZ $cntn2^{-/-}$ mutants exhibited no nucMLF defects. To assay for defects in the sensorimotor circuits of RB neurons in *cntn2* mutants, touch-evoked escape responses was evaluated. Wild type and mutants

larvae exhibited normal escape responses when touched on the head. In contrast, mutants were less responsive than wildtype siblings when touched in the trunk, suggestive of putative defects in RB circuits. Together, these data support distinct roles for Cntn2 in the development and function of neural circuits in zebrafish.

Title: The spinal muscular atrophy with pontocerebellar hypoplasia gene vrk1 regulates neuronal migration through an amyloid-β precursor protein-dependent mechanism

Authors: *H. VINOGRAD-BYK[1], T. SAPIR[2], L. CANTARERO[3], P. LAZO[3], S. ZELIGSON[1], R. ORLY[2], P. RENBAUM[1], E. LEVY-LAHAD[1];
[1]Med. Genet. Inst., Shaare Zedek Med. Ctr., Jerusalem, Israel; [2]Mol. Genet., Weizmann Inst. of Sci., Rehovot, Israel; [3]Hosp. Universitario de Salamanca, Salamanca, Spain

Abstract: Spinal muscular atrophy with pontocerebellar hypoplasia (SMA-PCH) is an infantile SMA variant with additional manifestations, particularly severe microcephaly. We previously identified a nonsense mutation in Vaccinia-related kinase 1 (*VRK1*), R358X, as a cause of SMA-PCH. VRK1-R358X is a rare founder mutation in Ashkenazi Jews, and additional mutations in patients of different origins have recently been identified. VRK1 is a nuclear serine/threonine protein kinase known to play multiple roles in cellular proliferation, cell cycle regulation, and carcinogenesis. However, VRK1 was not known to have neuronal functions before its identification as a gene mutated in SMA-PCH. We show that *VRK1*-R358X homozygosity results in lack of VRK1 protein, and demonstrate a role for VRK1 in neuronal migration and neuronal stem cell proliferation. Using shRNA *in-utero* electroporation in mice, we show that Vrk1 knockdown significantly impairs cortical neuronal migration, and affects the cell cycle of neuronal progenitors. Expression of wild-type human VRK1 rescues both proliferation and migration phenotypes. However, kinase-dead human VRK1 rescues only the migration impairment, suggesting the role of VRK1 in neuronal migration is partly noncatalytic. Furthermore, we found that VRK1 deficiency in human and mouse leads to downregulation of amyloid-β precursor protein (APP), a known neuronal migration gene. APP overexpression

rescues the phenotype caused by Vrk1 knockdown, suggesting that VRK1 affects neuronal migration through an APP-dependent mechanism.

Title: Impact of voluntary exercise during adolescence on cognitive performance in a touchscreen operant chamber during adulthood

Authors: ***J. O'LEARY**[1], C. BROUWERS[1], N. BROSENS[1], O. F. O'LEARY[1,2], J. F. CRYAN[1,2], A. M. SULLIVAN[1], Y. M. NOLAN[1];

Abstract: Background: Adolescence is a critical period for postnatal brain maturation and thus a time for increased susceptibility to developing emotional and cognitive disorders. Exercise during adulthood has been shown to increase hippocampal neurogenesis and enhance cognition (Creer *et al*., 2010, van Praag *et al*., 2005). However, the impact of exercise during adolescence on the brain and behaviour in adulthood remains to be fully elucidated. The aim of this study was to determine the impact of voluntary exercise during adolescence on neural plasticity and performance in a hippocampal neurogenesis-dependant location discrimination task in rodents during adulthood. **Methods:** Adolescent male Sprague Dawley rats (4 weeks) were divided into a sedentary control group (n = 10) and an exercise group (n = 10). All rats were pair housed in either standard housing or with continuous access to a running wheel and were trained to use a touchscreen operant chamber. Four weeks later, rats (8 weeks) were trained to discriminate between the locations of two adjacent identical stimuli. Inter-stimulus distance was varied with a small inter-stimulus distanced probe (small separation) and large inter-stimulus distanced probe (large separation). Upon acquisition, the reward location was switched and the rats were required to complete the task. Task acquisition was assessed by trials to criteria and reversal learning was measured by the number of acquisitions/switch reacquisitions. Immunohistochemical analysis (using antibodies targeting BrdU/NeuN and PSD-95) is currently underway to determine the

impact of exercise on neural plasticity in the hippocampus and prefrontal cortex. **Results:** Rats ran an average of 1.7km per day during the adolescent period (P28-56). Voluntary exercise enhanced reversal learning in rats subjected to the location discrimination task that assessed both the small separation ($p < 0.05$) and large separation ($p < 0.05$). Exercise readily enhanced reversal learning when the task was challenging (i.e. small inter-stimulus separation) ($p < 0.05$). Interestingly, acquisition of the location discrimination task was affected by inter-stimulus distance but not exercise. **Conclusions:** Growing evidence suggests that experience during early life has a significant impact on behaviour and cognitive processes in later life. These findings suggest that exercise readily improved reversal learning, a prefrontal cortex-dependent process, particularly when the task was challenging. Investigations into the impact of exercise during early life on adult neural plasticity are ongoing.

Title: Aripiprazole sensitization: Adolescence to adulthood in the conditioned avoidance response model and pcp model.

Authors: *E. D. FREEMAN[1], J. LIN, 68526[1], C. CHOW[1], C. DAVIS[2], M. LI[2];
[1]Psychology, [2]Univ. of Nebraska-Lincoln, Lincoln, NE

Abstract: The present study investigated repeated aripiprazole (ARI) treatment and the long term consequences of ARI sensitization in adolescent male and female rats, and to determine whether ARI sensitization transfers to olanzapine (OLZ) and/or clozapine (CLZ) using two behavioral tests of antipsychotic activity. In experiment 1, male and female Sprague-Dawley rats were first trained to acquire avoidance response, and then they were tested for conditioned avoidance response (CAR) under vehicle and ARI (10 mg/kg) on P46-50. After two retraining sessions, rats were challenged with ARI (1.5 mg/kg, subcutaneously, (sc); P70), OLZ (0.5 mg/kg, sc; P73), CLZ (5 mg/kg, sc; P76) and again with ARI (1.5 mg/kg, sc; P84). On the challenge days, both male and female rats previously treated with ARI had significantly lower avoidance than the vehicle group, and females made significantly more avoidances than males in both ARI and vehicle groups. Further, on the OLZ and CLZ challenge days, prior ARI treatment seemed to increase sensitivity to OLZ exposure, however, this increase was not significant. In

study 2, we examined sex difference of ARI sensitization in the PCP-induced hyperlocomotion model. Male and female Sprague-Dawley rats (P43-47) were first treated with aripiprazole (ARI; 10 mg/kg, sc) and tested in the PCP (3.2 mg/kg, sc)-induced hyperlocomotion model for five consecutive days. Then a challenge test with ARI (3 mg/kg, sc; P76), OLZ (.5 mg/kg, sc; P80), CLZ (5 mg/kg, sc; P84) and again with ARI (3 mg/kg, sc; P84) was administered. Through the 5 drug test days, there was a sex difference response to either ARI or VEH repeated treatment during adolescence in which females demonstrated increased motor activity as compared to males overall. During the drug treatment period, repeated ARI treatment inhibited the PCP-induced hyperlocomotion, and this inhibition was progressively increased across the 5-day period in both males and females, suggesting a sensitization effect. Moreover, females demonstrated increased motor activity as compared to males. On the challenge day, rats previously treated with ARI showed a stronger inhibition of PCP-induced hyperlocomotion (i.e. sensitization) than those previously treated with vehicle. Similarly, rats also showed an ARI sensitization to OLZ or CLZ on challenge days. Collectively, results from this experiment demonstrated a sex difference in response to ARI and enhanced inhibition of PCP-induced hyperlocomotion in the animals that were pretreated with ARI as compared to controls. Specifically, it appears that ARI reduces PCP-induced increases in locomotor activity and this effect appears to be more robust in males.

Title: Investigating the paranodal domain structure of myelinated axons in the medial prefrontal cortex of adolescent male and female rats

Authors: *E. TAVARES[1], A. SILVA-GOTAY[2], W. M. VARGAS[2], H. N. RICHARDSON[1]; [1]Psychological and Brain Sci., [2]Neurosci. and Behavior Program, Univ. of Massachusetts - Amherst, Amherst, MA

Abstract: Oligodendrocytes are glial cells that wrap segments of fatty myelin sheaths around axons in mature neurons, providing insulation and promoting faster propagation of electrical

signals along the axon. Efficient neurotransmission depends on tight organization and clustering of ion channels close to ("paranodal") and within ("nodal") the Nodes of Ranvier—the small unmyelinated sections of the axons located between segments of myelin sheaths. During adolescent development, myelin sheaths are still being formed on axons within brain regions that are involved in reward evaluation and decision-making abilities such as the prefrontal cortex. It is important to understand how myelin is formed around prefrontal axons during adolescence and whether this differs in males and females. Proliferation and cell death of oligodendrocytes is higher in females, which is thought to reflect more turnover of myelin in females. This sex difference observed in myelin turnover may affect the dynamics of axo-glial interactions that are necessary for efficient neurotransmission in myelinated axons. In the present study, we aimed to investigate whether there are sex differences in the formation of the nodes of Ranvier and surrounding structures, including the paranodal region—one of the axonal domains dependent on oligodendrocyte myelination in adolescent animals. Contactin-associated protein (caspr) is one of the cell-adhesion molecules dedicated to the formation of axo-glial contacts at the paranodal region of the nodes of Ranvier. Using immunofluorescence and confocal microscopy, we immunolabed caspr in the prefrontal cortex and forceps minor of the corpus callosum and measured nodal length (caspr gap), diameter (caspr width), and length-to-diameter ratio of mid-adolescent male and female rats. There were no sex differences in nodal length or diameter detected in any of the regions examined. However, the nodal length-to-diameter ratio in the forceps minor appears to be consistent in females (*ratio* = 1.22, *SD* = 0.01) and more variable in males (*ratio* = 1.24, *SD* = 0.14), whereas the average ratio did not differ between sexes. It is important to note that this was observed at only one time point, which did not allow us to visualize the progression of nodal and paranodal development throughout adolescence. Future studies with more developmental time points might help uncover the dynamics of nodal and paranodal development in the adolescent prefrontal cortex.

Title: chronic adolescent stress impairs spatial working memory in adult female rats

Authors: *R. MORANO;
Psychiatry, Univ. of Cincinnati, Cincinnati, OH

Abstract: During adolescence in rodents, the central nuclei that regulate the hypothalamic-pituitary-adrenocortical (HPA) axis, including the amygdala, hippocampus and prefrontal cortex are continuing to develop. These brain regions are densely populated with glucocorticoid receptors making them susceptible to plastic changes due to chronic glucocorticoid exposure. Our lab has previously shown that late adolescence is a period of increased vulnerability to the effects of chronic stress (PND 50 at initiation of stress) as indicated by somatic indices and increased basal corticosterone in male rats. Our lab has also shown that adult female rats (PND 101) exposed to chronic stress during the late adolescent period (PND 45-58) have a blunted HPA axis response to a novel stressor and increased immobility in the forced swim test. In the current study, male and female Sprague-Dawley rats were exposed to three weeks of chronic variable stress during adolescence with a focus on late adolescence. Our hypothesis for this experiment was that adolescent chronic stress would lead to enduring deficits in cognition and executive behavior in adult males and females. Separate cohorts of these animals were tested in adulthood for fear conditioning and delayed spatial win-shift (DSWS) to assess deficits in behavioral flexibility caused by adolescent chronic stress. Neither males nor females stressed in adolescence showed differences in the conditioning or extinction of the conditioned stimulus when compared to previously unstressed controls. However, the females exposed to adolescent stress exhibited a decrease in freezing to the conditioned stimulus when the recall of extinction was tested. Adolescently stressed females made more across phase and within phase errors on day 1 of testing and more within phase errors on day 3 of testing in the DSWS when compared to no stress controls. In contrast, there was a main effect of chronic stress during adolescence to reduce the overall errors in the DSWS in the adult males. These results suggest that the long-term effects of chronic adolescent stress are sex-specific, whereby females are more susceptible to altered stress responsiveness and impaired behavioral flexibility.

Title: Effect of pubertal delay and social stress on hippocampal connectivity in adolescent female rhesus macaques.

Authors: *M. PINCUS[1], J. GODFREY[1], E. FECZKO[2], E. EARL[2], C. KELLY[3], M. WILSON[1], D. FAIR[2], M. SANCHEZ[1];
[1]Emory Univ., Atlanta, GA; [2]Oregon Hlth. & Sci. Univ., Portland, OR; [3]Trinity Col., Dublin, Ireland

Abstract: The hippocampus plays a pivotal role in fear learning and regulation by contextually gating fear responses through its connections to the amygdala and medial prefrontal cortex (mPFC). Chronic stress impairs extinction-related mPFC-hippocampus long-term potentiation in animal models, and exposure to stressors during military service has been found to be associated with enhanced functional coupling (FC) in this circuitry. Adolescence is marked by enhanced fear learning, suggesting that fear learning circuitry may be affected by pubertal development. In support of this view, the hippocampus has been shown to undergo structural and functional changes during puberty. Given that stress and puberty may both modulate fear learning circuitry, we examined whether the development of hippocampal circuits are affected by chronic psychosocial stress and puberty-induced elevations of estradiol (E2) in adolescent female macaques. As part of a longitudinal study using social subordination as a model of psychosocial stress, female macaques were randomly assigned to either experience puberty spontaneously (n=34), or receive monthly injections of the GnRH agonist Lupron from 14-36 months of age to delay puberty (n=36). Resting state fMRI scans were acquired post-pubertally (43-46 months) and in a preliminary analysis we tested for effects of rank, Lupron treatment, and pubertal timing on hippocampal functional connectivity (FC) with mPFC and amygdala using linear regression. Because stronger mPFC-hippocampal FC was associated with delayed pubertal onset (BA32: β = 0.046, 95% CI [0.003, 0.088]; BA25: β = 0.077, 95% CI [0.025, 0.127]), we ran the statistical models controlling for pubertal onset, and found that Lupron-treated females had weaker mPFC-hippocampal FC than untreated controls (BA32: β = -0.424, 95% CI [-0.768, -0.004], BA25: β = -0.690, 95% CI [-1.289, -0.228]), suggesting that Lupron effects may be due to lower E2 levels even during the pre-pubertal period. Lower social rank was associated with higher mPFC-hippocampal FC (BA32: β = 2.664, 95% CI [0.472, 3.958], BA25: β = 3.200, 95% CI [0.455, 4.197]), which may reflect a greater stress load or an adaptation for improved contextual fear responses in an unpredictable social environment. Taken together, these data suggest that E2 levels, pubertal timing and chronic stress impact the maturation of mPFC-hippocampal circuitry during adolescence, which may have implications for contextual fear learning and regulation. Further analysis will assess whether the observed mPFC-hippocampal FC differences are

associated with variability in emotion regulation behaviors and stress physiology in adolescent females.

Title: Role of CB1 receptor signaling in the regulation of afferent-evoked plasticity in the prefrontal cortex *In vivo*

Authors: *H. M. MOLLA, D. R. THOMASES, K. Y. TSENG;
Dept. of Cell. and Mol. Pharmacol., The Chicago Med. Sch. At RFUMS, North Chicago, IL

Abstract: The adolescent maturation of the prefrontal cortex (PFC) is characterized by a number of structural and functional changes. Developmental augmentations of both GABAergic and glutamatergic transmission contribute to the maturation of cognitive function and the normative integration of afferent inputs. Basolateral amygdala (BLA) afferents evoke a non-developmentally regulated prefrontal LTP, while ventral hippocampus (vHipp) afferents elicit an age-dependent prefrontal LTD. Coinciding with these changes is a developmental downregulation in the expression of cannabinoid receptor-1 (CB1R) mRNA in the medial PFC. However, the functional significance of this downregulation of CB1Rs and its role in prefrontal afferent processing is not fully understood. Here we assessed the role of CB1R mediated transmission in the regulation of prefrontal long-term plasticity evoked by the vHipp and the BLA in both adolescent (P30-40) and adult (P>60) rats. We found that local prefrontal application of the CB1R inverse agonist AM251 (4 μM) does not affect the normal expression of vHipp-evoked prefrontal LTD. In contrast, a transient facilitation of BLA-evoked LTP is observed in adult rats. This input-specific sensitivity indicates CB1R tone regulates the PFC response to BLA inputs. Moreover, the facilitation of BLA-evoked prefrontal LTP by AM251 was found to be age-dependent, with no observable effects in the adolescent PFC, indicating a change of CB1R transmission during adolescence. Interestingly, local infusion of the CB1R agonist Win 55,212-2 (3 μM) both attenuates the expression of BLA-evoked prefrontal LTP and transiently enhances the expression of vHipp-evoked prefrontal LTD. Taken together these data indicate CB1 transmission developmentally regulates prefrontal long-term plasticity in an input-specific manner.

Title: Neuroimmune signaling in the nucleus accumbens underlying the adolescent critical period for drugs of abuse

Authors: ***A. M. KOPEC**, S. C. SWEAT, N. R. AYRE, S. D. BILBO;
Psychology and Neurosci., Duke Univ., Durham, NC

Abstract: During adolescence, the reward circuitry in the brain is undergoing rapid development, rendering it particularly vulnerable to external influences during this time, including drugs of abuse. Adolescent drug users have poor adult outcomes, including addiction-related behaviors and other mental health disorders. Microglia, the resident immune cells of the brain, can respond directly to opioid drugs (Hutchinson et al. 2010, Schwarz et al. 2013), and increasing evidence points to a critical role for these cells in addiction. Interestingly, male rats that receive morphine during a short period in adolescence (postnatal days 37-54; P37-54) have increased rates of reinstatement (relapse) later in life, and this effect is contingent on neuroimmune signaling in the nucleus accumbens (NAc) during adolescence (Schwarz and Bilbo 2013). However, the mechanisms by which neuroimmune signaling persistently alters the neural circuitry of the NAc and thus lastingly alters behavior, remain unknown. To begin to understand how neuroimmune signaling may be dysregulated by adolescent drug use, we first sought to characterize the role of neuroimmune signaling throughout the natural development of the NAc. Tissue was collected from male and female rats at P20, P30, P38, and P54 for immunohistochemical, gene expression, and protein analyses. The data indicate that neuron-microglia communication brokers, including fractalkine and CD200 signaling pathways, may be regulated in a sex-specific manner during NAc development. Interestingly, there may also be sex-specific morphological regulation of microglia during development. Collectively, these data suggest that the development and/or regulation of neuroimmune signaling in the NAc may be sexually dimorphic during the adolescent period. These results will be of considerable interest to investigate further, as they may suggest the need for differential treatment of males and females suffering from addiction.

Title: Differential effects of paradoxical sleep deprivation on adolescent and adult mice

Authors: ***L.-H. TUAN**[1], L.-J. LEE[1,2,3];
[1]Grad. Inst. of Anat. and Cell Biol., [2]Grad. Inst. of Brain and Mind Sci., [3]Ctr. for Neurobio. and Cognitive Sci., Natl. Taiwan Univ., Taipei, Taiwan

Abstract: Sleep insufficiency has become a serious health issue. In the modern society, most of the people, including the adolescence, do not obtain enough sleep.Since adolescence is a critical period for brain development, the consequences of insufficient sleep during adolescence should be concerned. In this study, we examined the acute effects of 72-hour paradoxical sleep deprivation (SD). Five weeks old and 10-12 weeks old male C57/BL6 micewere used. The two time points were chosen to represent the periods of adolescence and adulthood, respectively.SD for 72 hours were conducted using modified multiple platform method, in which mice were put in on small platforms(3 cm in diameter) surrounded by water and allowed to move freely from one platform to another. For mice kept in the home cage and on big platforms, sleep time was not limited and used as controls. All three groups of mice were kept under 12 h/12h light/dark cycle.Mice of SD and control groups were examined in behavioral, neurochemical and histological aspects. Our results showed that the short-term spatial memory, examined by Y-maze spontaneous alternation test,was affected by 72-hour paradoxical SD in adolescent mice but not in adult mice. The complexity of granule cells in dentate gyrus (DG)was reduced after SD in adolescent but minimal changes were observed in adult animals.There was an increase of spine density in DG granule cell after 72-hour paradoxical SD in adolescent and notin adult SD animals. Our results indicated the adolescent mice are relatively more sensitive to SD than the adult mice. Sufficient sleep during adolescent period is important for cognition and the brain development.

Title: Arginine vasopressin expression mediates paternal influence on female offspring aggression in Peromyscus californicus

Authors: *C. YOHN, A. LEITHEAD, E. A. BECKER;
Psychology, St. Joseph's Univ., Philadelphia, PA

Abstract: Paternal investment in the biparental and territorial California mouse (*Peromyscus californicus)* boosts pup survival and shapes adult offspring social behavior. Male offspring that experience high levels of paternal retrievals during postnatal development exhibit increased aggressive behavior and arginine vasopressin immunoreactivity (AVP-ir) in the bed nucleus of the stria terminals (BNST) in adulthood. Since offspring experience a transient surge in Testosterone (T) in response to paternal retrievals and AVP is androgen dependent during development, we posit these long-term changes in brain and behavior are likely a consequence of the elevated T levels. While this powerful relationship between paternal care and offspring development has been demonstrated in males, the father-daughter relationship has only recently been examined. Similar to male offspring, paternal retrievals induce both transient increases in T during early development and aggressive behavior in adult female *Peromyscus californicus* offspring. In the present study, we investigated whether similar neural mechanisms underlie the behavioral transmission between fathers and daughters. Since females experience an increase in T similar in magnitude to male offspring, and because AVP is associated with adult female aggression, we hypothesized that AVP expression in the female brain will change in response to paternal high levels of paternal care. To explore this aim, female *Peromyscus californicus* offspring were randomly assigned to either a high or low care condition during postnatal days 15-21 when paternal retrieval behavior is the highest. At adulthood, focal animals were randomly assigned to either one resident-intruder test or to immunohistochemical analysis of AVP within the social regions of the brain. Our results support previous studies showing that high paternal care females have shorter attack latency’s than females from the low paternal care offspring. Additionally preliminary data suggests that females from the high care group have higher AVP-ir expression in the bed nucleus of the stria terminalis (BNST) and paraventricular nucleus (PVN) than offspring from the low care group with a positive relationship emerging between BNST and PVN. Thus, AVP is a likely mechanism underlying the transmission of aggressive behavior between father and daughter. Additionally, given the role of the PVN in the HPA response, our data illustrates a paternally induced sensitivity to stressors in female offspring.

Title: Gonadal steroids at puberty drive organizational effects on inhibitory neurotransmission in the mouse frontal cortex.

Authors: *D. PIEKARSKI[1], J. R. BOIVIN[2], A. W. THOMAS[1], L. WILBRECHT[1]; [1]Univ. of California, Berkeley, Berkeley, CA; [2]Univ. of California, San Francisco, San Francisco, CA

Abstract: The age at puberty onset is advancing in the developed world (Aksglaede et al., 2009; Euling et al., 2008) and early puberty is associated with heightened risk for development of neuropsychiatric illness (Deardorff et al., 2007; Whittle et al., 2012; Deardorff et al. 2013; Graber, 2013). Pubertal onset also potentially plays a causal role in the closure of juvenile forms of plasticity that are permissive for dramatic reorganization of cortical connectivity and function (Lenneberg, 1967; Doupe and Kuhl, 1999). Inhibitory neurotransmission is thought to play a major role in regulating cortical sensitive periods in primary sensory cortex (Werker and Hensch, 2015) and may play a similar role in association cortex (Piekarski et al., in review). We have found that inhibitory neurotransmission onto pyramidal neurons matures in the mouse frontal cortex through the adolescent period (Vandenberg et al., 2015). To investigate the effects of pubertal steroids on the maturation of the frontal cortex, we developed a mouse model of earlier puberty in female mice using estradiol and progesterone injections. We also delayed pubertal onset using ovariectomy. Using slice electrophysiology to probe the maturation of neurotransmission in the frontal cortex layer 2/3 pyramidal neurons, we found miniature inhibitory post synaptic currents (mIPSCs), a measure of synaptic inhibition, increase in frequency and amplitude across adolescent development. The rise in mIPSC frequency was shifted to an earlier timepoint after gonadal steroid injection and prepubertal ovariectomy prevented this increase. Hormone treatment after ovariectomy was sufficient to rescue the

mIPSC frequency increase. Postpubertal ovariectomy, however, had no effect on mIPSC frequency. In control experiments in primary somatosensory cortex, gonadal steroid related changes in mIPSCs were not observed. These data suggest that gonadal steroids have an organizational effect on the maturation of inhibitory neurotransmission in the frontal cortex in the female brain. These data provide a potential mechanism by which puberty onset may affect the increased vulnerability for depression and anxiety observed after puberty in girls and alter the capacity for plasticity in association cortex.

Title: Social defeat stress during adolescence impairs the maturation of GABAergic function in the adult prefrontal cortex

Authors: *E. FLORES-BARRERA[1], D. R. THOMASES[1], A. CABALLERO[1], J. S. CARTER[2], K. E. GRANT[2], J. A. ROSENKRANZ[1], K. Y. TSENG[1];
[1]Cell. and Mol. Pharmacol., Rosalind Franklin Univ. of Med. and Sci., North Chicago, IL; [2]Dept. of Psychology, DePaul Univ., Chicago, IL

Abstract: Early life exposure to emotionally salient stressors is thought to contribute to the development of maladaptive behavioral patterns later in life, many of which are associated with aberrant functioning of prefrontal-mediated cognitive processing. However, the mechanisms underlying such developmental disruption remain unclear. Here we asked whether a disruption of prefrontal maturation could underlie the enduring cognitive impairments resulting from repeated social stress during adolescence (from postnatal day -P- 32 to P38). Using electrophysiological measures, we found that the normal inhibitory control of afferent drive is lacking in the adult prefrontal cortex (PFC) of rats that underwent adolescent social defeat. Results from local field potential recordings and ventral hippocampal stimulation revealed that the pattern of prefrontal response observed in the social defeat stress group resembles that seen in the immature PFC of naïve juvenile rats. At the cellular level, such inhibitory disruption in the PFC was associated with a state of increased AMPA/GABA ratio in layer V pyramidal neurons,

mainly due to a selective downregulation of local GABAergic transmission. A similar dysregulation of prefrontal GABAergic function was observed in rats that underwent social defeat stress during the P42-48 adolescent period. However, no deficits in PFC inhibition were observed when the repeated social defeat stress was presented during late adolescence (i.e., P50-55) or adulthood (P75-80). Collectively, these results indicate that social defeat stress during early and mid-adolescence had the most potent and enduring impact on PFC function and maturation, in particular at the level of local GABAergic function. As fine-tuning of PFC output and behavior are highly dependent on the activity of local inhibitory interneurons, impaired GABAergic maturation resulting from social defeat stress during adolescence is expected to elicit enduring deficits in prefrontal-dependent cognitive functions.

Title: Hedonic reward consumption is elevated in male, but not female, adolescent rats

Authors: ***A. T. LIU**[1], Y. CUI[1], N. P. MURPHY[2], N. T. MAIDMENT[2], S. B. OSTLUND[1]; [1]Dept. of Anesthesiol. and Perioperative Care, UC Irvine, Irvine, CA; [2]Hatos Center, Dept. of Psychiatry and Biobehavioral Sciences, Semel Inst. for Neurosci., UCLA, Los Angeles, CA

Abstract: There is growing evidence that decision-making is profoundly altered during adolescence, resulting in excessive risk-taking behavior and heightened vulnerability to drug addiction. Determining how adolescent neural development impacts more fundamental aspects of reward processing will be key to improving our understanding of risky adolescent behavior. The current study investigated this issue by characterizing microstructural patterns of voluntary reward consumption in peri-adolescent and adult rats. We first conducted a quasi-longitudinal experiment tracking consumption of a highly palatable sweetened condensed milk solution (SMC, 10%) over several weeks in non-deprived male and female rats, beginning at PD 30 (covering adolescence) or PD 60 (covering early adulthood). We found that male, but not female, adolescent rats showed a pronounced increase in SCM intake (normalized for bodyweight)

around PD 50 (roughly corresponding to male puberty). This effect was associated with various alterations in the microstructure of licking behavior, with males showing larger mean lick volumes, as well as longer and more frequent bouts of licking early in the session, prior to the induction of satiety. To more precisely target hedonic aspects of feeding, we conducted a second experiment examining saccharin consumption in male adolescent and adult rats. We found that, here too, male adolescent rats showed elevated reward consumption, particularly early in test sessions, prior to satiety, an effect that appeared to be driven by longer bouts of active licking behavior. Ongoing experiments are examining whether this heighted reward processing during male adolescence is associated with alterations in reward-related neural activity.

Title: Neuronal signal molecules in developing and adult Dreissena, an environmental biofouling mollusk

Authors: *I. BATTONYAI[1], E. E. VORONEZSHKAYA[2], A. OBUKHOVA[2], L. P. NEZLIN[2], K. ELEKES[1];

Abstract: Zebra mussel (*Dreissena polymorpha*) is an invasive molluscan species, appearing in Lake Balaton (Hungary) by 1930 and becoming soon thereafter its ruling bivalve. The question arises what might be the basis of this successful invasive behavior. Apart from pure ecological considerations, one, maybe a less considered possibility is the role of early sensory elements capturing chemical signals, followed by proper adaptive responses. Therefore, as a first attempt, we have investigated the development of the nervous system of trochophore and veliger *Dreissena* larvae, with special attention to their signal molecule (serotonin [5-HT] and FMRFamide [Fa]) content. On the other hand, we have also investigated the innervation of the

byssus retractor muscle (BRM), which is responsible for anchoring the animals to different surfaces, with special emphasis to 5-HT, Fa and choline acetyltransferase (ChAT) containing elements, respectively. Immunohistochemical techniques combined with confocal laser microscopy were used for visualization. The first 5-HT containing cells were found in sensory cells of the apical organ (AO) as early as in 16-18 hours post-fertilization free living trochophores. It was followed by the appearance of a caudal and a stomach sensory cell at 48-60 hours veliger stage. A similar developmental scenario was characteristic for the Fa-immunreactive (IR) system, starting however later by 32 hours. Pharmacological experiments proved the role of 5-HT in accelerating larval swimming activity, paralleled with enhanced relative immunofluorescence intensity. Increased salinity evoked similar changes in the 5-HT and Fa immunoreactivities. Our findings suggest the suitability of the larval nervous system and behavior of *Dreissena* to test the effect of different environmental cues to better understand the neuroethological background of the invasive behavior. The innervation pattern of the BRM was characterized by varicose networks formed by both 5-HT- and Fa-IR fibers with branching into thin fibers supplying the finger-like extrusions of the BRM. ChAT immunoreactivite fine processes was also present along the finger-like extrusions, referring to additional cholinergic regulation of muscle function. It is assumed that the BRM stands under aminergic and peptidergic influence, modulating cholinergic transmission. Our results provide a good basis for further physiological and pharmacological characterization of the BRM as a possible target of different environmental cues.

Title: Behavioral pharmacology of planaria (Giardia) as a model for glutamate excitotoxicity.

Authors: M. SCRIBNER, *B. R. MILLER;
Texas Wesleyan Univ., Fort Worth, TX

Abstract: Planaria (*Girardia*) are a useful animal model in neuropharmacology as their neurological features are strikingly similar to human and other vertebrate neuronal physiology. One example is that glutamate serves as the primary excitatory neurotransmitter in humans and planaria. Importantly, in humans, neuronal over excitation with glutamate results in neurodegeneration; a key feature in a number of neurological diseases. To date, the effects of glutamate have yet to be extensively studied in planaria, which can serve as a model organism for drug discovery. The purpose of this study is to establish a glutamate concentration-response curve for planarian behaviors. This endeavor was accomplished by observing planaria in increasing glutamate concentrations and identifying four behaviors. Here, single planarians were placed into petri dishes with a marked 0.5 x 0.5 cm grid and video-recorded for 5 minute intervals. There were 11 tested glutamate concentrations ranging from 0.001 mM to 250 mM. Four behaviors were analyzed; two standard planarian behavioral metrics, line crosses and C/S-shaped convulsions, as well as, two newer metrics, crenellations and corkscrews. The most sensitive metrics were C/S-shaped convulsions (at 3.0 mM and greater) and corkscrew (at 1.0 mM and greater). Therefore, we suggest that planaria are a useful model organism for evaluating glutamate excitotoxicity.

Title: Requirement of IP_3R function and SOCE in dopaminergic interneurons for *Drosophila* flight

Authors: *S. SADAF[1], S. P. SANE[2], G. HASAN[3];
[1]Natl. Ctr. For Biol. Sci., Bangalore, India; [2]Natl. Ctr. for Biol. Sci., Bangalore, India; [3]Natl. Ctr. for Biol. Scirnces, Bangalore, India

Abstract: Neural circuits respond to various stimuli, integrate the signals and give rise to accurately tuned animal behavior. The environmental cues are detected by cells and are further relayed down through specific sets of participating cells in the form of biochemical signals. One of the robust signaling molecules is calcium (Ca^{2+}), which acts as a second messenger. The neural circuits are shaped and modulated during different developmental stages and Ca^{2+} signals play an important role in their development, maintenance and modulation.
In bilaterally symmetric animals, behaviors such as movement of limbs in mammals or

movement of wings in fruit flies (*Drosophila melanogaster*) are dictated by specific sets of symmetric as well as asymmetric neural circuits (1). In *Drosophila*, for example, the left and the right wings have their own sets of motor machinery including motor neurons and their target muscles. Neurotransmitters and neuromodulators form the functional connectivity between the various components of the neural circuit.
In our previous study, we had investigated the functional connectivity between dopaminergic neurons in the second thoracic segment. The a-a' dopaminergic connect to the ventral unpaired medial (VUM) neuron. The VUM sends axonal projections to the b1Mns and together this circuit mediates coordinated bilateral wing movements (2).
IP_3R, dSTIM and Orai, are the three major components of the GPCR activated IP_3 signaling pathway and contribute to intracellular Ca^{2+} signals. The role of the IP_3 signaling components in dopaminergic neurons was shown in our recent paper (3).
This study focuses on the requirement of IP_3 signaling and store operated calcium entry in the T2 dopaminergic neurons for flight and bilateral wing movements.
We find that the IP_3R, dSTIM and Orai function is required in dopaminergic neurons for free flight in the cylinder drop test. IP_3R function and store operated Ca^{2+} entry (SOCE) is required in dopaminergic neurons to mediate bilateral coordination of wing movements during flight initiation and cessation. Furthermore, this required can be narrowed down to a paired set of dopaminergic neurons in the adult thoracic ganglion. The IP_3 signaling is mediated through the GPCR, mAcR, for flight and wing movement coordination

Title: A diurnal rhythm in head histamine in wild-type and white *Drosophila*

Authors: *J. BORYCZ[1], J. A. BORYCZ[1], I. A. MEINERTZHAGEN[1,2];
[1]Dept. Psychology & Neurosci., [2]Dept. Biol., Dalhousie Univ., Halifax, NS, Canada

Abstract: Histamine (HA) is a photoreceptor neurotransmitter in arthropods. Most released HA is recycled via conjugation with β-alanine to form β-alanylhistamine (carcinine), a process mediated by Ebony in the epithelial glia that surround photoreceptor terminals in the first optic neuropil, and the carcinine is then transported back to photoreceptors where Tan mediates its hydrolysis to liberate HA and β-alanine. We have previously reported that light-induced HA-release is potentiated in the mutant chalky of *Calliphora erythrocephala,* most probably because in the absence of screening pigments more photoreceptors are overstimulated by scattered light than in wild-type. We have also shown that head histamine content is reduced roughly by half in the white-eyed mutants of different species e.g. *Drosophila*, *Musca*, *Calliphora* and *Sarcophaga.* In our observations the *Drosophila* mutant *white*^{1118} (w^{1118}) kept for 3 days in constant light had its head histamine decreased by almost 40% whereas the same treatment did not alter head HA in the wild-type (Borycz et al. 2008). Here, we wanted to analyse whether there is a diurnal rhythm in head histamine in wild-type *Drosophila* and if this is affected in the mutant *white*. Animals were kept at 24ºC at 12/12 h light-dark cycle. They were collected in 6-hour intervals, starting from the beginning of the light phase. During the light phase head HA increases slowly in the wild-type reaching a maximum at 12 hours of light, an increase by 18% over the lowest HA content observed at the beginning of the light phase. In contrast in the head of the w^{1118} HA slightly decreases by 5% at midday and by 12% at the end of the light phase. In the dark phase HA in the head of wild-type flies decreases slowly, losing the 18% which was gained during the light phase. In contrast HA increases during the dark phase in the head of w^{1118} mutant flies, restoring the 12% lost during the light phase. Our results demonstrate that HA content oscillates daily in the fly's brain. Lack of the White transporter in w^{1118} reverses this rhythm and diminishes the fly's ability to efficiently recycle and/or synthesize HA during the light phase, although the loss can be recovered in darkness by the w^{1118} mutant.

Title: Temporal profiling of the phosphorylation of CaMKII at Threonine 286 & Threonine 305 following classical conditioning

Authors: *H. WAN[1], G. KEMENES[2];
[2]Sussex Neurosci., [1]Univ. of Sussex, Brighton, United Kingdom

Abstract: CaMKII is considered a 'memory' molecule and has two important phosphorylation sites, threonine 286 (T286) and threonine 305 (T305). The activation of CaMKII, due to phosphorylation at T286 (pT286), is known to be pivotal for both memory acquisition and initiation of synaptic plasticity, the substrate for learning as well as late memory consolidation. Following the initial phosphorylation at T286, there is a second wave of CaMKII phosphorylation at T305 (pT305). CaMKII inhibitory phosphorylation at T305 functions to inactivate CaMKII and is involved in synaptic metaplasticity and refining of memory and has recently been reported to be necessary for on-going memory consolidation. Despite a plethora of studies on CaMKII over the last 3 decades, it is still unclear when CaMKII becomes inactivated following activation or if the activation-inactivation process is repeated several times during memory consolidation. Here we present a temporal profile of the phosphorylation of CaMKII at T286 and T305 following classical conditioning in *Lymnaea*, an established invertebrate model. Following single-trial classical conditioning with amyl acetate as the conditioned stimulus and sucrose as the unconditioned stimulus, the buccal and cerebral ganglia that are important for learning and memory were collected at hourly intervals after training. The samples were subjected to western blotting, with specific antibodies for CaMKII, pT286-CaMKII and pT305-CaMKII. We found that the changes in the levels of pT286-CaMKII and pT305-CaMKII show an opposing trend: pT286-CaMKII is swiftly increased, at 2 min post conditioning, and gradually decreases thereafter, returning to the baseline level at 6h post conditioning. pT305-CaMKII, however, displays changes at a much slower pace by gradually increasing from 1h onwards. The enhanced pT305, however, does not return to the baseline level, rather, it is still maintained at 6h post conditioning. Temporal profiling of pT286-CaMKII and pT305-CaMKII for the time points after 6 h is ongoing. The completed study will, for the first time, reveal the detailed temporal characteristics of CaMKII phosphorylation during memory consolidation, and open new avenues for research on later memory processes, i.e. memory reconsolidation and storage. These results will also have wider implications for studies of other serine/threonine kinases.

Abstract: During metamorphic development of the tenebrionid beetle, *Zophobas morio*, the number and type of neurons in the terminal abdominal ganglion that show serotonin-like immunoreactivity (SLI) changes in a complex and dynamic fashion. In the larval stage, the hindgut is innervated by two pairs of serotonin-containing efferent neurons; the segmental system of serotonin interneurons is present in incomplete form; and three further pairs of serotonin interneurons are present. As metamorphic development proceeds, one pair of efferent neurons and two of the extra pairs of interneurons lose SLI. The segmental system of serotonin interneurons develops and reaches completion as a pattern of 1-3 pairs of neurons per neuromere depending on segment identity. The temporal changes in the number and type of neurons involve gain, loss, or persistence of SLI. In most instances, these changes seem to arise from up- or down-regulation of serotonin content in existing neurons. These dynamics correlate with the reported temporal variation of hemolymph titer of the molting hormone, 20-hydroxy ecdysteroid.

Title: Automated behavioral pharmacology assay using planaria (Girardia) in a 3-D printed apparatus.

Authors: *D. POE[1], A. CORNWALL[2], M. TAYLOR[2], B. MILLER[2];
[1]UNT Syst. Col. of Pharm., Univ. of North Texas Hlth. Sci. Ctr., Fort Worth, TX; [2]Texas Wesleyan Univ., Fort Worth, TX

Abstract: Several key features make planaria an effective biological model for neuroscience studies. Namely, planaria exhibit cephalization and a nervous system that has remarkable similarities to mammalian species. Planarian membranes are highly permeable to pharmacological agents which allows for tight dosing and concentration controls. Additionally, planaria are inexpensive making them suitable for use in a wide range of settings including undergraduate studies. One challenge of using planaria as behavioral models is that often the data are hand-coded making the task labor-intensive and heavily dependent on inter-coder reliability. To address these challenges, we constructed an apparatus which incorporates several off-the-shelf components and novel 3-D printed components into an automated system. The system consists of five lanes which may be simultaneously managed by a single operator. Each lane is a modular, self-contained testing environment which can be filled with pharmacologically neutral or active media depending on the testing protocol. A single planarian is placed at the top of a lane and exposed to an ultraviolet-light stimulus. The planarian's photophobic taxis away from that stimulus is monitored by two infrared beam-break sensors and these data are relayed by an Arduino microcontroller to either the operator's computer or to a secure digital (SD) non-volatile memory card. Using this apparatus, we have found that completing a protocol where n = 30 can be achieved in less than two hours and that we are able to plot a glutamate dose-response in concentrations as low as 0.01 μM. Indeed, this system allows for high-throughput, high-accuracy testing using the planaria model in addition to being readily scalable, easy-to-use and cost-efficient. The system is ripe for implementation in any laboratory doing behavioral neuropharmacology with planaria as well as in undergraduate learning laboratories.

Title: Dysfunctional NMDA receptors affect excitatory transmission causing neurological disease

Authors: *L. FEDELE[1], R. J. HARVEY[2], T. G. SMART[1];
[1]Neuroscience, Physiol. and Pharmacol., Univ. Col. of London, London, United Kingdom; [2]UCL Sch. of Pharm., London, United Kingdom

Abstract: N-methyl-D-aspartate receptors (NMDARs) are ionotropic glutamate receptors that together with α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptors and kainate (KA) receptors mediate the vast majority of fast excitatory neurotransmission in the central nervous system. Given this role, any dysfunction to excitatory neurotransmission is likely to have a severe impact on brain physiology and subsequent behaviour. Recently, *de novo* mutations have been reported in several subunits (GluN2) of the NMDAR for patients exhibiting a number of neurological disorders such as: autism spectrum disorders, epilepsies, and intellectual disabilities characterised by marked cognitive impairments[1]. Here, we have used a combination of techniques based on structural modelling, site-directed mutagenesis and electrophysiology to deduce how selected mutations located to the NMDAR ion channel and to the GluN2 subunit N-terminal domain are affecting NMDAR function. We hypothesized that these missense mutations could be correlated with the phenotypes of the patients and we therefore sought to understand the molecular mechanisms that underlie the clinical disease profiles.

We developed a complete tetrameric structural model of the NMDAR (GluN1-GluN2A,B) based upon the recently reported crystal structures of the NMDARs[2,3]. By using more than one such template we were able to include several loop regions of the NMDAR in one structure, some of which were deleted in the crystallography studies. This facilitated the identification of the locations for mutated (pathogenic) residues and helped us deduce their potential impact on neighbouring amino acids and receptor structure. The functional effects of several mutants of the GluN2 subunit resulted in both loss-of-function and gain-of-function phenotypes. The most profound phenotypes were used for expression studies in cultured neurons revealing how these mutations can compromise excitatory synaptic transmission in patients.

Overall, our results suggest that some of the NMDAR mutations can be correlated with the phenotypes of the patients. In addition, our analyses will be beneficial in indicating what pharmacotherapeutic interventions are most likely to be successful as potential treatments.

Abstract: Experience-dependent activation of N-methyl-D-aspartate receptors (NMDARs) at hippocampal excitatory synapses initiates structural changes that support memory formation. These structural changes include greater dendritic arbor complexity and increased spine number. Two predominant signaling properties of NMDARs that have been independently linked to hippocampal plasticity are calcium conductance into the postsynaptic spine and direct intracellular protein interactions. These properties vary with the composition of the NMDAR such that, compared to NMDARs with GluN2A subunits, NMDARs with GluN2B subunits conduct calcium for a longer period after activation and display greater affinity for the obligatory synaptic plasticity protein, CaMKII. As such, it is not possible to determine the separate influences of these NMDAR properties by switching the entire GluN2 subunit. To overcome this obstacle, we constructed GluN2 chimeras and expressed them in transgenic mice. Conductance regulating domains exist in the GluN2 extracellular amino (A)-terminus and transmembrane (TM) regions. Intracellular signaling domains exist in the intracellular carboxy (C) terminus. We generated two transgenic mouse lines, one having the A-terminus and TM regions of GluN2A fused to the C-terminus of GluN2B (termed ABc) and, vice versa, the other line having the A-terminus and TM regions of GluN2B fused to the C-terminus of GluN2A (termed BAc). These chimeric GluN2 subunits were expressed using the tet-off expression system with tetracycline transactivator protein (tTA) expression under transcriptional control of the CaMKII minimal promoter. tTA expression was seen in many forebrain regions, but predominantly in hippocampal pyramidal cells. To examine how separate NMDAR properties regulate dendritic structure, we measured neuromorphological characteristics of hippocampal pyramidal neurons in young adult mice (1-2 months of age), utilizing both Golgi-Cox staining and Thy-1 GFP

fluorescence methods. Bright field and confocal microscopy, along with Neurolucida tracing, were employed to measure dendritic arbor complexity and spine density. Preliminary results demonstrate a trend for reduction in dendritic branching and spine density in ABc compared to BAc and wild-type (WT) animals. Given the heavy GluN2A background in adult mice, these results suggest potentially stalled development due to greater presence of the GluN2B C-terminus. These findings advance understanding of the means by which NMDARs regulate dendritic plasticity/development by better defining the region of the GluN2B subunit that restrains hippocampal development.

Title: Exploration of the molecular mechanisms underlying the effect of L-lactate on long term memory

Authors: E. K. IBRAHIM[1], O. AL ZAHRANI[1], H. FIUMELLI[1], *P. J. MAGISTRETTI[2,1]; [1]Biol. and Envrn. Sci. and Engin., King Abdullah Univ. for Sci. and Technol., Thuwal, Saudi Arabia; [2]Ecole Polytechnique, Lausanne, Switzerland

Abstract: In the brain, glycogen, the storage form of glucose, is exclusively localized in astrocytes (Magistretti and Allaman, 2015). Glycogenolysis leads to the production of L-lactate, which is shuttled to neurons for ATP production. Interestingly, L-lactate was recently shown to be not only a source of energy, but also a signaling molecule to neurons. This was demonstrated through the inhibition of L-lactate production or transport in an inhibitory avoidance paradigm, where the rodents developed amnesia. This inhibition of memory consolidation was rescued by L-lactate and not by equicaloric glucose emphasizing that L-lactate acts as a signaling molecule as well (Suzuki et al., 2011). A recent study in our laboratory suggests that the action of L-lactate takes place through a cascade of molecular events via the modulation of N-methyl-D-aspartate receptor (NMDAR) activity (Yang et al., 2014). Since NADH produced similar results to those seen with L-lactate, it was hypothesized that the action of the latter is based on altering the redox state of the cell, in particular in view of the fact that redox-sensitive sites are present on the NMDAR. However, the precise molecular mechanism underlying the apparent change in the NMDAR activity is not fully elucidated. The objective of this study is to explore those

mechanisms.
It has been previously shown that when key cysteines on NMDARs are reduced, the activation of NMDAR is amplified and vice versa (Choi et al., 2001). Accordingly, we introduced point mutations at those cysteines on different subunits of NMDAR and expressed them in HEK cells. Fluorescence microscopy for calcium imaging was used to monitor NMDARs activity. Initial results show three main effects of L-lactate on wild type NMDAR composed of the subunits NR1/NR2A. First, faster kinetics of the initiation of response compared to control. Second, L-lactate increased the percentage of cells having a maximum amplitude value greater than 7.5 fold of the baseline calcium signal as compared to the control. Finally, L-lactate significantly decreased the decay rate of the calcium signal to the basal calcium levels of the cells during the washout. In addition, using the mutated NR2A subunit (C87S, C320S) led to changes in the amplitude of the NMDAR responses to glutamate. Thus we have now established a system where the effect of L-lactate can be tested on NMDAR subunits mutated at different redox-sensitive sites.
In conclusion, these results confirm in transfected HEK cells that L-lactate has potentiating effects on NMDAR activity, possibly through the alteration of the redox state of the cell.

Title: Optophysiological characterization of endogenous and recombinant glutamate receptors in neuroblastoma cells

Authors: *N. A. ALMUZAINI[1], K. S. JONES[2];
[1]Biol., Howard Univ., Arlington, VA; [2]Biol., Howard Univ., Washington, DC

Abstract: Optophysiology is an emerging physiological technique that uses genetically encoded sensors such as GCaMP6 to visualize neuronal activity *in vivo* and *in vitro*. Optophysiology may present several advantages over traditional electrophysiological methods and in this study we set

out to determine the feasibility of using the optical calcium sensor, GCaMP6s, to monitor the functional expression of *N*-Methyl-D-aspartate receptors (NMDARs). N-methyl-D-aspartate receptors (NMDARs) are one of three major ionotropic glutamate receptors that mediate excitatory transmission in the central nervous system. To demonstrate the feasibility of our approach we utilized the neuroblastoma cell line, SK-N-SH. Undifferentiated SK-N-SH cells expresses very low levels of NMDA receptor subunits. However, treatment with retinoic acid (RA) has been shown to confer a neuron-like morphology in SK-N-SH cells and increase the expression of NMDA receptors (Pizzi et al, 2002). We hypothesized retinoic acid-treatment would induce sufficient expression of functional NMDARs to permit optophysiological detection and characterization by GCaMP6s in SK-N-SH cell. To test this hypothesis, SK-N-SH cells were cultured in 30 uM RA for 14d. After 14d, the cells were transfected with a plasmid encoding GCaMP6s. Calcium imaging was performed two days later on a spinning-disk confocal microscope. Calcium signals were evoked from SK-N-SH cells by bath applying the NMDAR co-agonist 100 uM NMDA and 100 uM D-Serine. Agonist-dependent calcium signals were detected from RA-treated cells, but not vehicle-treated cells. Moreover, the calcium signals were abolished by co-application of NMDA receptor antagonists, MK-801 and ketamine. We also examined the impact of RA on the morphology of SK-N-SH cells. We found that RA-treatment lowered the density of proliferating cells, increased average neurite length, and increased staining for neuron specific markers such as Tuj1, MAP2, and GluN1/GluN2B receptors. These data demonstrate the feasibility of using GCaMP to physiologically characterize a calcium-permeable, ligand-gated ion channel and confirm the ability of RA to induce a neuron-like morphology in SK-N-SH cells.

Title: Epilepsy-associated GRIN2A mutations - functional analysis and pharmacological rescue of phenotypic deficits

Authors: ***L. ADDIS**[1], J. K. VIRDEE[2], L. R. VIDLER[2], D. A. COLLIER[2], D. K. PAL[1], D. URSU[2];

Abstract: Epileptic encephalopathies are severe brain disorders characterized by seizures and abundant epileptiform activity contributing to cognitive, language and behavioural regression. An electro-clinical spectrum of epileptic, cognitive and language disorders can be formed from the frequent focal epilepsy Rolandic epilepsy, to the severe epileptic encephalopathies Landau-Kleffner syndrome (LKS) and continuous spikes and waves during slow-wave sleep (CSWS). Around 20% of cases in this spectrum are caused by mutations in the NMDA receptor *GRIN2A*. Here we analyse the disease mechanisms of ten human missense *GRIN2A* mutations and investigate strategies for restoration of functional deficits observed in our study. Human *GRIN2A* mutation constructs were transiently transfected into HEK-293 cells along with human *GRIN1* to form heterotetrameric receptors. Confocal imaging of immunolabelled cells showed normal membrane expression for wild type (WT) and some mutant constructs. However protein from two NR2A mutants were trapped in the endoplasmic reticulum with no surface expression, and another three mutants had vastly reduced levels of membrane expression compared to WT. Western blotting revealed mutations located before the C-terminal domain of NR2A had reduced total expression compared to WT, with those that disrupt the disulphide-bond of cysteine residues expressing less than 50% of WT protein levels. Single cell calcium imaging and patch clamp recordings showed that mutations both at the interface of NR1 and NR2A and close to the glutamate binding site had a robust effect on glutamate affinity, causing a rightward shift of 4 to 30-fold in the concentration dependence for glutamate. These mutations also decreased the affinity of the NMDA receptor to glycine. Mutations located after the glutamate binding domain responded as wild-type to glutamate and glycine. Single cell patch clamping also revealed alterations in the Mg^{2+} block of some mutants. High-throughput calcium flux assays showed that all studied mutations do not appear to alter NMDA receptor antagonist pharmacology. We were able to rescue the phenotype of the mutations with reduced glutamate affinity after treatment with an NR2A-selective positive allosteric modulator. Taken together these data suggest that mutations across *GRIN2A* affect the expression and function of the receptor in different ways, with the end result of altered NMDA receptor currents and neuronal excitability. Careful molecular profiling of these patients is essential for effective personalised treatment options.

Title: Peculiarities of agonist activity of homocysteine on GluN2A- and GluN2B-containing NMDA receptors

Authors: *S. M. ANTONOV[1], D. A. SIBAROV[1], P. A. ABUSHIK[1], R. GINIATULLIN[2]; [1]Sechenov Inst. of Evolutionary Physiol. and Biochem., Saint-Petersburg, Russian Federation; [2]Dept. of Neurobio., A. I. Virtanen Inst. for Mol. Sciences, Univ. of Eastern Finland, Kuopio, Russian Federation

Abstract: Hyperhomocysteinemia, a condition with excessive level of homocysteine (HCY) in plasma, leads to neuronal death and underlies a variety of cardiovascular and neurodegenerative disorders. Whereas it is known that HCY can interact with NMDA receptors (NMDARs), its action on receptors composed by different subunit composition is almost unknown. Therefore, using cultured cortical neurons and heterologous expression in HEK293T cells we tested the agonist activity of HCY on GluN1/2A or GluN1/2B subunit containing NMDAR. In neurons responses induced by 50 μM HCY, in contrast to current induced by 30 μM NMDA (both in the presence of 30 μM Gly) were often comparable in amplitude but much faster declined to the baseline. In calcium-free external solution the decrease of NMDA evoked currents was abolished, suggesting the Ca^{2+}-dependence NMDAR desensitization. In contrast, in calcium-free conditions HCY evoked currents still declined almost to the baseline suggesting calcium-independent desensitization. In HEK293T cells HCY activated NMDARs of GluN1/2A and GluN1/2B subunit compositions with EC_{50}s of 9.7 ± 1.8 μM and 61.8 ± 8.9 μM, respectively. Recombinant GluN1/2A receptors, however, did not desensitize by HCY, whereas GluN1/2B receptors were almost fully desensitized by HCY. Thus, HCY is a high affinity agonist of NMDARs preferring the GluN1/2A subunit composition. Our data suggest that HCY induced native NMDAR currents in neurons are mainly mediated by the 'synaptic type' GluN1/2A NMDARs. This implies that in hyperhomocysteinemia HCY may contribute to postsynaptic responses along with excitotoxicity via GluN2B-containing extrasynaptic receptors.

Med., Blacksburg, VA; [6]Biochem. and Pharmacol., Edward Via Virginia Col. of Osteo. Med., Blacksburg, VA

Abstract: The N-methyl D-aspartate (NMDA) receptors play a crucial role in normal brain function and pathogenesis of neurodegenerative and psychiatric disorders. Functional tetraheteromeric NMDAR contains two obligatory GluN1 subunits and two identical or different non-GluN1 subunits that include six different gene products; four GluN2 (A-D) and two GluN3 (A-B) subunits. The heterogeneity of the subunit combination determines the distinct function of NMDARs. All GluN subunits contain an extracellular N-terminal Domain (NTD) and ligand binding domain (LBD), a transmembrane domain (TMD) and an intracellular c-terminal domain (CTD). The interaction between the GluN1 and coassembling GluN2 or N3 subunits through the LBD has been proven crucial for defining receptor deactivation mechanisms that are unique for each combination of NMDAR. Modulating the LBD interactions has great therapeutic potential. In the present work, by amino acid point mutations and two electrode voltage clamp electrophysiology techniques, we have studied the role of LBD interactions in determining the effect of well characterized pharmacological agents including agonists, competitive antagonists, uncompetitive antagonists and allosteric modulators. The results reveal that the LBD interaction between GluN1&2 through GluN1 Y535 and E781 plays a decisive role in determining affinity and efficacy of competitive, but not noncompetitive, antagonists. These findings revitalize the modulatory role of LBD interactions that can be exploited to design and develop novel NMDAR based therapeutic agents.

Title: Regulation of striatal neuronal NMDAR trafficking by palmitoylation: Potential role in Huntington disease

Authors: *R. KANG[1], L. WANG[2], S. S. SANDERS[3], K. ZUO[2], M. R. HAYDEN[3], L. A. RAYMOND[2];
[2]Dept. of Psychiatry and Djavad Mowafaghian Ctr. for Brain Hlth., [3]Dept. of Med. Genet. and Ctr. for Mol. Med. and Therapeut., [1]Univ. of British Columbia, Vancouver, BC, Canada

Abstract: N-methyl-D-aspartate receptors (NMDAR) play a critical role in excitatory synaptic signaling, and alterations in the balance of synaptic and extrasynaptic NMDARs impact neuronal survival. Recent studies show enhanced extrasynaptic GluN2B-type NMDAR activity in striatal neurons in the YAC128 mouse model of Huntington disease (HD), resulting in increased and decreased activation of cell death and survival pathways, respectively, that contribute to striatal vulnerability to degeneration in HD. Mechanism(s) of altered GluN2B trafficking remain unclear, however. Notably, the huntingtin (Htt) protein directly interacts with palmitoyl acyltransferases DHHC17 and DHHC13, also called huntingtin-interacting protein-14 (HIP14) and HIP14-like (HIP14L) and mutant Htt expression results in reduced interaction with HIP14 and HIP14L, leading to decreased palmitoylation of several synaptic proteins in YAC128 mice. Furthermore, GluN2B palmitoylation on two C-terminal cysteine clusters regulates its trafficking to surface membrane and synapses in cortical neurons. Here, we investigated whether altered GluN2B palmitoylation contributes to its accumulation at extrasynaptic sites in striatal neurons from YAC128 HD mice. We found reduced GluN2B palmitoylation in YAC128 striatum. Moreover, NMDAR containing the cluster II (but not cluster I) palmitoylation-resistant mutant GluN2B (GluN2B 5CS) showed significantly enhanced surface expression in striatal neurons in wild-type (FVB/N) corticostriatal co-cultures, mimicking the increased striatal GluN2B surface expression observed in YAC128 co-cultures. Importantly, the increased striatal surface GluN2B 5CS was restricted to extrasynaptic membranes. Furthermore, we found HIP14 and HIP14L differentially interact with and palmitoylate GluN2B on the two clusters *in vitro*. These findings suggest potential roles of HIP14 and HIP14L in altered GluN2B-NMDAR trafficking in striatal neurons of an HD mouse model.

Title: Human anti-GluN1 antibody-mediated effects on NMDA receptor subtypes.

Authors: ***J. A. PANZER**, A. RATTELLE, D. R. LYNCH;
Neurol., Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: N-methyl-D-aspartate receptors (NMDARs) are heterotetrameric glutamate receptors composed of two GluN1 subunits, and two other subunits, most often GluN2A or GluN2B. Neuronal NMDARs are located at both synaptic and extrasynaptic locations; signaling from receptors at synaptic sites can promote synaptic plasticity and cell survival whereas extrasynaptic signaling has been linked to neurodegeneration. GluN2A-containing receptors may be more prevalent at synaptic sites, while GluN2B containing receptors are often associated with extrasynaptic sites. In the autoimmune disease anti-NMDAR encephalitis, antibodies bind the GluN1 subunit of the NMDAR, resulting in psychosis, altered consciousness, seizures, dyskinesias, and autonomic dysfunction. Antibodies bind to the GluN1 extracellular amino-terminal domain, resulting in transient stabilization of the receptor's open conformation, and subsequent NMDAR hypofunction due to receptor cross-linking and internalization. We have found that the impact of patients' anti-GluN1 antibodies on NMDARs is modulated by the GluN2 subtype, resulting in distinct action on GluN2A versus GluN2B containing receptors. We have further evaluated the effects of antibody binding on neuronal activity, synaptic versus extrasynaptic NMDARs, and downstream signaling. Our results may explain why the clinical symptoms of the disease do not precisely replicate global NMDAR knockdown, and may point towards potential therapeutic targets in anti-NMDAR encephalitis. The unique properties of these antibodies also raise the possibility of their use as tools to explore NMDAR function.

Title: Lateral mobility of synaptic NMDA receptors in hippocampal slices

Authors: ***A. L. MCQUATE**, A. BARRIA;
Physiol. and Biophysics, Univ. of Washington, Seattle, WA

Abstract: NMDARs are fundamental coincidence detectors necessary for the induction of synaptic plasticity. Adjusting NMDAR synaptic content, whether by receptor insertion via intracellular vesicles or lateral diffusion between extrasynaptic and synaptic compartments, could play a substantial role defining the characteristics of the NMDAR-mediated EPSC, which in turn would mediate the ability of the synapse to undergo plasticity. Electrophysiological evidence from cultured autapses and fluorescence imaging of single molecules in dissociated hippocampal neurons both suggest that NMDARs diffuse laterally between extrasynaptic and synaptic compartments. However, attempts to demonstrate this motility in hippocampal slices thus far have failed. To test for lateral mobility in hippocampal slices, we rapidly blocked synaptic NMDARs using MK-801. Following a five-minute washout period, we recovered roughly 50% of baseline NMDAR EPSC amplitudes. The degree of the observed recovery was proportional to the amount of induced blockade. These results indicate that the lateral diffusion of NMDARs could be a mechanism by which synapses rapidly adjust parameters to fine tune synaptic plasticity.

Title: Characterisation of two NMDA NR2B subunit (grin2b) antagonists across tests of impulsivity and attention

Authors: *G. A. HIGGINS[1,2], L. B. SILENIEKS[1], C. MACMILLAN[3], J. SEVO[3], F. D. ZEEB[4,2], S. THEVARKUNNEL[1];

Abstract: NMDA NR2B subtype selective antagonists are currently in clinical development for a variety of indications, including major depression. We previously reported the selective NR2B NMDA antagonists Ro 63-1908 (Ro) and traxoprodil, increased premature responding in a rat 5-choice serial reaction time task (5-CSRTT) suggesting an effect on impulsive action (Higgins et al (2005) Psychopharmacology 179: 85-98). The present studies extend these investigations to a Go-NoGo and delay discounting task, and the 5-CSRTT under test conditions of both regular (5s) and short (2-5s) multiple ITI. Dizocilpine was included for comparison. Male Long-Evans rats were used in all experiments. Both Ro 63-1908 (0.1-1mg/kg SC) and traxoprodil (0.3-3mg/kg SC) increased premature and perseverative responses in both 5-CSRT tasks and improved attention when tested under a short ITI test condition (e.g. premature: vehicle: 11.8$\pm$2.6 responses, Ro 1 mg/kg: 68.3$\pm$17.6 responses; $P<0.01$). Ro 63-1908 but not traxoprodil increased motor impulsivity (false alarms) in a Go-NoGo task (vehicle: 8.1$\pm$1.5 responses, Ro 1 mg/kg: 14.3$\pm$2.5 responses; $P=0.02$). Dizocilpine (0.01-0.06mg/kg SC) affected both measures of motor impulsivity and marginally improved attention. In an ascending delay discounting test of impulsive choice, both dizocilpine and Ro 63-1908 decreased impulsive choice (i.e. increased choice for the larger, delayed reward), while traxoprodil showed a similar trend (e.g. AUC measure: vehicle: 1006$\pm$167 units, Ro 1 mg/kg: 1358$\pm$199 units; $P<0.01$). Motor stimulant effects were evident following Ro 63-1908 (0.3-3 mg/kg SC), but not traxoprodil (1-10 mg/kg SC) treatment - although no signs of motor stereotypy characteristic of dizocilpine dose (>0.1 mg/kg) were noted. The findings of both NR2B NMDA antagonists affecting measures of impulsive action and compulsive behavior may underpin emerging evidence to suggest glutamate signaling through the NMDA NR2B receptor plays an important role in behavioural flexibility (e.g. Holmes et al (2013) Nature Neurosci. 16: 1101-1110.). The profiles between Ro 63-1908 and traxoprodil were not identical, perhaps suggesting differences between members of this drug class on behaviour.

Title: N-Methyl-D-Aspartate (NMDA) receptor glycine site agonist shows pronounced subtype-dependent pharmacological profiles

Authors: ***M. JESSEN**[1,3], K. FREDERIKSEN[1], H. BRÄUNER-OSBORNE[3], P. KILBURN[2], A. DAMHOLT[1];

Abstract: *N*-methyl-D-aspartate (NMDA) receptors are tetrameric ligand-gated ion channels involved in memory function as well as neurological diseases, including depression and Parkinson's disease. There are several small-molecule binding sites on the different NMDA receptor subtypes and understanding of the pharmacology of these receptors can facilitate the development of new therapeutic agents. A single study has shown that the glycine site partial agonist D-cycloserine (DCS) has antidepressive effects in clinic. Subtype-dependent differences in agonist efficacy have previously been reported for DCS. Using two-electrode voltage-clamp electrophysiology, we have characterized compound I, a potent glycine site agonist, at four different human NMDA receptor subtypes (GluN1/2A-2D) expressed in *Xenopus* oocytes. Compound I showed pronounced subtype-dependent pharmacological activity, and was a full agonist at GluN1/2A (I_{max} = 100% relative to glycine, EC_{50} = 66 nM), a super agonist at GluN1/2C (I_{max} = 476%, EC_{50} = 8 nM), and was a partial agonist at GluN1/2B and GluN1/2D (I_{max} = 10% and 58%, EC_{50} = 14 nM and 33 nM respectively). This is intriguing, since compound I binds the glycine site of the GluN1 subunit, which is conserved in all four heteromeric receptors. To delineate the mode-of-action, compound I was tested on GluN1/2A receptors with three single point mutations (F484A, R523A, and T518L) in the glycine binding site. These three mutations greatly reduced compound I potency by 400- to 1100-fold at the four NMDA receptor subtypes without changing agonist efficacy relative to glycine, indicating that compound I binds in the GluN1 glycine binding pocket. The striking functional GluN1/2C selectivity of compound

I is unprecedented among any glycine site agonists evaluated, including DCS. Compound I is therefore an interesting tool compound for uncovering the mechanism of glycine site-mediated GluN2-dependent subtype selectivity and for future drug design.

Title: Investigating the impact of NMDA receptor hypounction on the synaptic integration of hippocampal neurogliaform cells

Authors: *R. CHITTAJALLU, J. C. WESTER, M. C. CRAIG, E. BARKSDALE, G. AKGUL, S. HUNT, C. FANG, X. YUAN, D. COLLINS, K. A. PELKEY, C. J. MCBAIN;

Abstract: Neural network dysfunction can result from excitation and inhibition imbalance, the latter being mediated by diverse interneuron (IN) subtypes each endowed with unique functional properties. Appropriate specification and synaptic incorporation into neural circuits of IN subtypes is critical for normal CNS function. Although perisomatic inhibition of principal cells, such as that imparted by parvalbumin-expressing (PV) basket cells, shapes network behavior the importance of dendritic inhibition in controlling excitatory output, generating oscillations and gating information flow is gaining more attention. Neurogliaform cells (NGFCs) are the prevalent family of dendritic targeting INs within the hippocampus yet one of the most understudied. NMDAR activity is central in many developmental and synaptic processes and their hypofunction, particularly in PV basket cells, is implicated to be causal in disorders such as schizophrenia and autism. Here, we show that NGFCs in the CA1 stratum lacanosum-moleculare (SLM) possess large synaptic NMDAR-mediated responses throughout postnatal development (~10-fold higher NMDAR/AMPAR ratio than in PV basket cells). We therefore examined the

relevance of NMDARs in NGFC development. To ablate NGFC NMDARs we crossed floxed *Grin1* knockout and *Htr3A*-cre:Ai14 mouse lines. NMDAR hypofunction resulted in lower density of TdTom+ cells in SLM and reduction of reelin expression, a marker for NGFCs, in the remaining tdTom+ cells. Functionally, although NMDAR knockout in NGFCs did not alter basic membrane and firing properties, an increase in AMPAR-mediated sEPSC frequency that progressively worsened during postnatal development was evident. The normal developmental trajectories of AMPAR-mediated sEPSC amplitude and paired pulse ratios were significantly retarded. Changes in AMPAR inward rectification suggestive of GluA2 loss was also observed and a marked misspecification of dendritic arborization was noted. These data demonstrate NMDAR hypofunction precipitates pre- and post-synaptic abnormalities in NGFCs. The predominant glutamatergic afferents impinging on NGFCs arise from two brain regions - layer III of medial entorhinal cortex and thalamic nucleus of reuniens. Using optogenetics, we are currently assaying whether the observed synaptic changes are afferent specific and hence may impact relative information processing between these brain structures and hippocampus. Future studies will be required to decipher the pathophysiological consequences of NMDAR hypofunction in NGFCs thus leading to further insight into the underlying molecular and synaptic etiology of neurodevelopmental disorders.

Title: Low-dose NMDAR antagonists increase the excitation/inhibition balance onto CA1 pyramidal cells causing disinhibition

Authors: *A. J. WIDMAN, L. L. MCMAHON;
Univ. of Alabama, Birmingham (UAB), Birmingham, AL

Abstract: Low-dose NMDAR antagonists, including ketamine, elicit rapid antidepressant responses in patients with Major Depressive Disorder (MDD) and in preclinical rodent models, although the anti-depressant efficacy is variable between mechanistically distinct NMDAR antagonists. Blocking NMDARs on pyramidal cells or on parvalbumin basket cells are proposed mechanisms to trigger the antidepressant effects, but the location of relevant NMDARs remains unclear. To date, no study has examined the most immediate effects of NMDAR inhibition on the excitation/inhibition (E/I) balance in hippocampus, a brain region negatively impacted by depression. To investigate whether NMDAR inhibition causes a net increase in excitation, we examined the effect of NMDAR antagonists on spontaneous IPSCs and EPSCs, evoked E/I ratio, and synaptically driven action potentials in hippocampal pyramidal cells in acute slices. Additionally, we tested whether three mechanistically different NMDAR antagonists: ketamine, a non-competitive antagonist, GLYX-13, a partial antagonist, and Ro 25-6981, a GluN2B subunit selective antagonist, all of which have antidepressant effects at low-dose, produce shared or distinct effects. Ketamine decreased both sIPSC frequency and amplitude, without altering either sEPSC frequency or amplitude, implicating a selective effect on inhibition. The E/I ratio increased following application of ketamine. Also, we found an increased probability that evoked subthreshold EPSPs will generate a synaptically driven action potential in the presence of ketamine, showing that pyramidal cells are disinhibited. GLYX-13 reduces spontaneous and evoked inhibition to a lesser degree and produces a less potent disinhibition compared to ketamine, which is likely explained by its partial agonist activity. Ro 25-6981 elicited a variable effect with sIPSC frequency increasing in some cells and decreasing in others. This was also observed with the E/I ratio and synaptically driven action potential probability. Ro 25-6981 increased inhibition in some cells and increased excitation in others, which may be due to a subset of interneurons having GluN2B-containing NMDARs. Together, our results show that ketamine and GLYX-13 shift the E/I balance towards excitation and disinhibit pyramidal cells, likely through targeting NMDARs on interneurons. Results also demonstrate that Ro 25-6981 does not increase the E/I balance suggesting mechanistically distinct NMDAR antagonists have different effects on synaptic circuit dynamics potentially providing a mechanistic understanding of the lower efficacy of GluN2B-selective NMDAR antagonists in treating depression.

Title: Structure activity relationships and mechanism of action of NMDA receptor positive allosteric modulators based upon 2-naphthoic acid

Authors: *K. SAPKOTA[1], G. FANG[2], M. W. IRVINE[2], E. BURNELL[2], G. CULLEY[2], D. CHOPRA[3], S. DRAVID[3], G. L. COLLINGRIDGE[4], D. E. JANE[2], D. T. Abstract: N-Methyl-D-aspartate (NMDA) receptor hypofunction is thought to significantly contribute to the symptoms of schizophrenia and, perhaps, autism. Thus, NMDA receptor positive allosteric modulators are potential therapeutics for the treatment of these conditions. Our laboratories have previously reported the properties of NMDAR PAMs based upon the phenanthroic acid with an alkyl chain. More recently, we have evaluated a family of related 6-alkyl-2-naphthoic acid analogues and find several highly effective NMDAR PAMs with optimal activity corresponding to a pentyl chain length with weak activity for propyl and butyl groups and inhibitory activity for an ethyl substituent. Polar substitutions along the alkyl chain generally inhibited PAM activity. Of the compounds identified, UBP684 and UBP753, were among the most effective in enhancing NMDAR responses at the four GluN1/GluN2 receptors (GluN1/GluN2A-GluN2D). The potentiation by these compounds is voltage-independent and is not blocked by saturating concentrations of agonist (L-glutamate plus glycine). Unlike that of a phenanthroic acid PAM (UBP512), UBP684 can bind to the closed state of the receptor. Using GluN1/GluN2A and GluN1/GluN2D receptors, we find that UBP684 slows deactivation time of the receptor. We have also found that when the glutamate binding site is locked in the agonist conformation by a disulfide bridge with two cysteine mutations in GluN2A, the potentiation is greatly diminished. However, locking the GluN1 glycine binding site in the agonist conformation does not reduce potentiation. These results are consistent with single channel analysis indicating that UBP684 potentiates by increasing the open probability and more effectively modulates gating steps controlled by the GluN2 subunit than by the GluN1 subunit. Computer modelling suggests that these compounds can bind in GluN1/GluN2 ligand binding domain (LBD) interface near the hinge of the LBD. In particular, the longer alkyl chain naphthoic acid analogues, which have PAM activity, are long enough to place the end of their alkyl chain near the hinge region of UBP684 in a hydrophobic pocket that would not tolerate polar substituents. By analogy to AMPA receptor PAMs, binding at this location can account for the NMDAR potentiation and slowed receptor deactivation of these modulators. These results suggest a mechanism of action

for the newly characterized NMDAR PAMs and structural insights that may lead to improved lead compounds for neuropsychiatric disorders.

Title: Protons exert distinct influences on the translocation of the M3 domains of GluN1 and GluN2A N-methyl-D-aspartate receptor subunits

Authors: ***N. N. JACKSON**[1], S. N. REID[2], K. S. JONES[1];
[1]Biol. Dept., Howard Univ., Washington, DC; [2]Anat., Howard Univ. Col. of Med., Washington, DC

Abstract: N-methyl-D-aspartate receptors (NMDARs) are one of three major ionotropic glutamate receptors that mediate excitatory transmission in the central nervous system. NMDAR current is strongly attenuated by extracellular proton concentration (pH), which can fluctuate dramatically during pathological states. Several amino acid residues in the transmembrane domain have been shown to contribute to the pH sensitivity of NMDA receptors, however, details of the biophysical mechanism remain unclear. The M3 transmembrane domain of NMDAR subunits undergo conformational rearrangement during channel activation, and we and others have used the Substituted Cysteine Accessibility Method (SCAM) to reveal that sulfhydryl specific modification of the NMDA receptors containing a cysteine substitution at the 7th alanine of the SYTANLAAF motif of the M3 domain (A7C) stabilizes the channel in an open state (Jones et al., 2002; Yuan et al., 2005).
NMDARs comprised from GluN1/GluN2B subunits are trapped in a non-conducting state by protons (Banke et al., 2005). In this study, we used NMDARs comprised from GluN1-A7C or GluN2A-A7C subunits to investigate the impact of protons on the conformational rearrangement of the M3 domain during gating. NMDARs current was measured in *Xenopus laevis* oocytes expressing wild-type or A7C mutant NMDAR subunits using two-electrode voltage-clamp electrophysiology. Proton inhibition was not significantly altered in NMDARs comprised from

GluN1-A7C or GluN2A-A7C subunits, but could be dramatically attenuated by co-application of agonists and 2-Aminoethyl methanesulfonate (MTSEA). Curiously, proton block was more rapidly attenuated by MTSEA modification of NMDARs composed from GluN2A-A7C subunit. Moreover, MTSEA modification increased the amplitude of current evoked from NMDARs comprised from GluN2A-A7C-containing receptors at all pH values. By contrast, MTSEA modification increased the amplitude of current evoked from GluN1-A7C-containing receptors only at pH values less than or equal to 7.3, and decreased the amplitude of current evoked at higher pH.
Together these findings suggest protons may impact the conformational rearrangement of NMDA receptor subunits by restricting the translocation of the channel gate. Moreover, these data suggest the gating elements of the GluN1 and GluN2A subunits have distinct sensitivities to pH and may adopt unique conformational states during channel activation.

Title: Endogenous expression of SAP97 in PV interneurons is correlated to decreased NMDAR synaptic activity

Authors: *R. C. FERRER FIERRO[1], A. BAEZ[2], L. WOLLMUTH[1];
[1]Dept. of Neurobio. and Behavior, [2]Stony Brook Univ., Stony Brook, NY

Abstract: Parvalbumin (PV) expressing interneurons are the most common subtype of GABAergic inhibitory interneurons in the cortex. PV interneurons play an essential role in cortical sensory processing and working memory and their dysfunction is associated to disease states such as schizophrenia and epilepsy. The inhibitory output of PV interneurons is driven by glutamatergic excitatory inputs, mediated by ionotropic glutamatergic receptors (AMPARs and NMDARs). The regulation and dynamics of glutamatergic receptors, including the number and subunit composition, will therefore have a strong impact on PV interneuron activity. SAP97 is a scaffolding protein capable of interacting with AMPARs and NMDARs, regulating synaptic trafficking and targeting of the receptors in a subtype and subunit specific manner. SAP97 expression is developmentally downregulated in PV interneurons, leading to two adult

subpopulations distinguished by the presence (SAP97+) or absence (SAP97-) of SAP97 (Akgul and Wollmuth, 2010 J Comp Neurol). Functionally, SAP97 expression in PV interneurons is causally associated to an increase in the frequency of AMPAR-mediated miniature EPSCs (mEPSCs) (Akgul and Wollmuth, 2013 J Neurosci). In the present study we address whether SAP97 expression has any effect on synaptic NMDARs. For that purpose, we use brain slice recordings of NMDAR-mediated mEPSCs from PV interneurons in layers 2-3 of primary visual cortex in juvenile and adult mice, combined with single cell RT-PCR to establish the endogenous expression of SAP97. Our results suggest that SAP97 expression has no effect in juvenile; but in the adult, contrary to the AMPARs, the presence of SAP97 was correlated to a decrease in the frequency of NMDAR-mediated mEPSCs. Consequently the two subpopulations of PV interneurons based on SAP97 expression would have a very different functional profiles, with SAP97+ interneurons having the excitatory input dominated by AMPARs, whereas SAP97- interneurons having both AMPAR and NMDAR components.

Abstract: At central synapses, presynaptic NMDA receptors (preNMDARs) typically enhance vesicle release, although the molecular mechanisms are largely unknown. Using quadruple whole-cell recordings, we explored the effect of preNMDAR blockade on spontaneous and evoked release onto layer-5 pyramidal cells in P11-17 mouse visual cortex acute slices. During 30-Hz firing, the GluN2B-specific NMDAR blocker Ro25-6981 (Ro) reduced both readily releasable pool (RRP) size (-36% ± 7%, n = 11 vs. controls -7.1% ± 5%, n = 11, $p < 0.05$) and replenishment rate (-31% ± 7% vs. 18% ± 7%, $p < 0.001$). In evoked release, preNMDARs thus indirectly increase release probability by upregulating the RRP replenishment rate, which a computer model showed improves signal to noise during high frequency firing. PreNMDAR blockade only reduced neurotransmission at firing frequencies above ~8.5 Hz, yet spontaneous release at ~2.5 Hz was also downregulated, suggesting independent mechanisms of regulation. To elucidate the mechanism, we tested if preNMDARs rely on the vesicle pre-priming and presynaptic scaffolding protein RIM1. Heterozygous RIM1αβ knockout (hetKO) mice exhibited decreased EPSC amplitude (32 ± 4 pA, n = 36 vs. controls 54 ± 10 pA, n = 22, $p < 0.01$) and increased paired pulse facilitation (-0.30 ± 0.05 vs. controls -0.47 ± 0.03, $p < 0.001$), indicating reduced release probability. During evoked release in RIM1αβ KO slices, preNMDAR blockade did not affect EPSC amplitude (96% ± 4%, n = 12 vs. 98% ± 10%, $p = 0.88$), RRP replenishment rate ($p=0.83$), or RRP size ($p=0.68$), while in RIM1αβ flox controls all three were reduced (52% ± 10%, n = 6, $p < 0.01$; -69% ± 5%, $p < 0.001$; and -42% ± 9%, $p < 0.01$; ANOVAs). Consistent with preNMDARs relying on RIM1, GluN2B also co-immunoprecipated RIM1. However, preNMDAR blockade still reduced spontaneous release rate in both hetKO and control slices (AP5 in hetKO 77% ± 5%, n=9, $p<0.01$ vs. control; AP5 in floxed controls 75% ± 3%, n=7, $p<0.001$; Ro in hetKO 83% ± 3%, n=7, $p<0.01$; Ro in wild type 82% ± 5%, n=10, $p<0.05$). We next explored if preNMDARs need RIM1 for scaffolding or for signaling. If the former, then preNMDAR-mediated bouton Ca^{2+} supralinearities should be absent in RIM1αβ KO mice. We found however, that the magnitude of Ca^{2+} supralinearities were indistinguishable between RIM1αβ KO and control animals (25% ± 4%, n= 26 vs. 26% ± 8%, n= 18, $p = 0.86$). Since preNMDAR-mediated Ca^{2+} supralinearities were unaffected in boutons of RIM1αβ KO animals, we conclude that preNMDARs signal via RIM1 to boost evoked neurotransmission during high frequency firing by indirectly increasing release probability, whereas preNMDARs regulate spontaneous release via an independent mechanism.

Title: Emerging role of GluN2D-containing NMDARs in modulating synaptic plasticity within the bed nucleus of the stria terminalis and anxiety/depressive-like behaviors.

Authors: *G. J. SALIMANDO[1,2,3,4,5], T. A. WILLS[6], D. G. WINDER[1,2,3,4,5];
[2]Mol. Phys. and Biophysics, [3]Vanderbilt Brain Inst., [4]Neurosci. Program in Substance Abuse, [5]Kennedy Ctr., [1]Vanderbilt Univ., Nashville, TN; [6]Cell Biol. and Anat., Louisiana State Univ. Hlth. Sci. Ctr., New Orleans, LA

Abstract: The bed nucleus of the stria terminalis (BNST) plays an important role in regulating affective stimuli such as stress and anxiety that have been well-established as precipitating factors for major depressive disorder. Our previous studies suggest an important role for GluN2B-containing N-methyl-D-aspartate receptors (NMDARs) in BNST long term potentiation (LTP), and in regulation of affective behaviors. We used a proteomic strategy to analyze BNST tissues and identify GluN2B-associated proteins within the region. One candidate of interest identified by this study was the GluN2D NMDAR subunit. Utilizing RNAscope® fluorescent *in* situ hybridization, we find that GluN2B mRNA is present in ~95% of observed BNST cells expressing corticotropin releasing factor (CRF) mRNA, and that ~70% of these CRF+ cells also express GluN2D mRNA. Because BNST CRF receptor signaling has been repeatedly shown to participate in the regulation of depression-like behaviors, we elected to explore the role of GluN2D-containing NMDARs in BNST function and behavior. We assessed baseline performance of GluN2D knockout (GluN2D-KO) and wildtype littermate mice across a range of behavioral tasks, including the elevated zero maze (EZM), open field (OF), light/dark box (L/D) and forced swim test (FST) to evaluate the subunit's role in regulating depressive phenotypes. We found that GluN2D-KO mice exhibit phenotypic profiles across these tasks consistent with increased anxiety- and depressive-like behaviors, a result that was noticeable under both group-housed and socially isolated conditions. Further, we are using the GluN2D knockout mouse to explore the potential role of GluN2D in BNST synaptic plasticity. Taken together, these data suggest that GluN2D-containing NMDARs may participate in regulating depressive/anxiogenic behavioral outputs.

Title: The role of protein phosphatase 1 in regulating NMDA receptor trafficking

Authors: ***A. M. CHIU**[1], T. TEDESCHI[1], A. SANZ-CLEMENTE[2];
[2]Dept. of Pharmacol., [1]Northwestern Univ., Chicago, IL

Abstract: N-methyl-D-aspartate receptors (NMDARs), fundamental components of the excitatory neuronal synapse, play key roles in numerous neurological processes including neuroplasticity and synaptic maturation. NMDARs are able to achieve these phenomenon through their ability to activate specific intracellular cascades in response to receptor activation. Which intracellular cascades are activated upon NMDAR activation is, in part, regulated by the subunit composition and localization of the receptor. Thus, a key aspect of NMDAR regulation and function is tight control over trafficking of the receptor.
Posttranslational modification is a crucial component of receptor trafficking. We have previously investigated a key regulatory aspect of NMDAR trafficking - phosphorylation of the GluN2B PDZ-binding domain. Phosphorylation of this site, by casein kinase 2, results in the disruption of GluN2B-containing NMDARs from synaptic scaffolding proteins. This, in turn, allows for the redistribution of NMDARs away from the synapse. More recently, our efforts have turn towards understanding how the PDZ-binding domain of GluN2B is dephosphorylated, as we hypothesize that the PDZ-binding domain must be dephosphorylated for NMDARs to be integrated into the postsynaptic density. Data generated from our lab has identified protein phosphatase 1 (PP1) as the phosphatase responsible for dephosphorylating GluN2B's PDZ-binding domain. Because PP1 is a constitutive phosphatase, we are currently working towards identifying the molecular mechanism governing PP1's ability to target and dephosphorylate GluN2B's PDZ-binding domain, as well as, understanding the ramifications of altering its activity. Understanding how PP1 exerts regulation on this posttranslational modification and its consequence on NMDAR trafficking and localization may be key to understanding how correct physiological NMDAR trafficking occurs and how this is altered in disease states.

Title: Physiological differences between the primary visual cortex and dorsolateral prefrontal cortex in primate

Authors: *S. YANG[1], M. WANG[2], M. ALTMAN[2], L. E. JIN[2], V. GALVIN[2], A. F. T. ARNSTEN[2], J. A. MAZER[2];
[1]Dept. of Neurobio., [2]Yale Univ., New Haven, CT

Abstract: NMDA receptors (NMDAR) subserve persistent neuronal firing of Delay cells during working memory in the dorsolateral prefrontal cortex (dlPFC) of nonhuman primates. In contrast, blockade of AMPAR has only subtle effects on dlPFC Delay cell firing, and the permissive depolarization of the synaptic membrane needed for NMDAR actions is carried out by acetylcholine, e.g via stimulation of alpha-7 nicotinic receptors. The relieance of dlPFC Delay cells on NMDAR has direct clinical relevance, as insults to NMDAR synapses in dlPFC can lead to working memory deficits and thought disorders in patients. Unlike the dlPFC, little is known about the modulation in the primary visual cortex (V1) of the primate. The current study directly compared glutamate receptor influences in an association area (dLPFC) to that in a sensory area (V1) by measuring the spatial receptive field (RF) of single neurons in V1 of the awake monkey while iontophoresis was used to deliver minute amounts of charged compounds near the recorded neuron. Changes in V1 responsivity were compared to changes in dlPFC Delay activity (putative working memory-related) in monkeys performing a visual spatial working memory task. In dlPFC, recent study found that Delay cell persistent firing was abolished by local NR2B NMDAR blockade or by systemic ketamine administration. AMPA receptors contributed background depolarization to sustain network firing, while AMPAR blockade had mixed effects on Delay cell firing, decreasing firing in some neurons, having no effect in others, or increasing firing. In V1, however, low doses of the NMDAR antagonist MK801 or the NR2B NMDAR antagonist Ro25-6981 had little effect on V1 neuronal firing, while high doses of MK801 or Ro25-6981 significantly decreased V1 response to visual stimuli. Interestingly, a low dose of the AMPAR antagonist CNQX significantly suppressed V1 neuronal firing, which was very different from its effects on dlPFC Delay activity. These data show that the modulatory circuitry

in V1 is fundamentally different from that in dlPFC, particularly the circuitry responsible for sustaining delay activity in the absence of visual stimulation in Delay neurons. This difference may account for the resilience of primary visual cortex to the effects of cognitive disorders such as Alzheimer's Disease.

Title: Effects on magnesium block and potentiation of non-pore lining residues in NMDA receptor transmembrane domains

Authors: ***M. WILCOX**[1], S. MESBAHI, 15217[2], M. KURNIKOVA, 15217[2], J. W. JOHNSON[1];
[1]Univ. of Pittsburgh, Pittsburgh, PA; [2]Carnegie Mellon Univ., Pittsburgh, PA

Abstract: NMDA receptors (NMDARs) are ionotropic glutamate receptors typically composed of two GluN1 and two GluN2 (GluN2A-D) subunits. Each GluN1 and GluN2 subunit contains an extracellular amino terminal domain (ATD) and ligand binding domain (LBD), a transmembrane domain (TMD) and an intracellular C-terminal domain (CTD). The TMD includes three membrane-spanning helices (M1, M3, M4), and a pore-lining reentrant loop (M2). All NMDARs composed of GluN1 and GluN2 subunits (GluN1/2A – GluN1/2D receptors) exhibit voltage-dependent channel block by external magnesium (Mg^{2+}); pore-facing asparagine (N) residues in the M2 regions are thought to form the Mg^{2+} binding site within the ion channel. Interestingly, mutation of an M2 residue in GluN1/2B receptors that is predicted to face away from the pore (GluN2B(W607)) results in loss of Mg^{2+} block (Williams et al., 1998). GluN2B(W607) is predicted to be nearby residues on the adjacent GluN1 M3 region, and may participate in intersubunit interactions. The GluN2A and GluN2B M2 and M3 regions are identical in sequence; in the GluN2A subunit, the W homologous to GluN2B(W607) (GluN2A(W606)) similarly faces the M3 region of the adjacent subunit. However, mutation of GluN2A(W606) results in only a moderate weakening of Mg^{2+} block (Williams et al., 1998). We further investigated the disparate effects on Mg^{2+} block of mutations of GluN2B(W607) and the

GluN2A(W606). Using homology modeling and MD simulations, we identified a residue in the GluN1 M3 region (GluN1(M634)) nearby GluN2A(W606) in GluN1/2A receptors and GluN2B(W607) in GluN1/2B receptors. We used whole-cell electrophysiological recordings from transfected tsA201 cells to examine responses of mutant and wildtype (WT) NMDARs to Mg^{2+}. We found that mutation of GluN1(M634) drastically decreases Mg^{2+} block in GluN1/2A receptors, but has little effect on Mg^{2+} block in GluN1/2B receptors. We also found that mutation of GluN2B(W607) causes augmentation of the previously demonstrated ability of Mg^{2+} to potentiate GluN1/2B receptor responses. Further examination of Mg^{2+} interactions with GluN1/2B receptors revealed that removal the ATD eliminated Mg^{2+} potentiation without affecting channel block by Mg^{2+}. These results reveal an asymmetry between GluN1/2A and GluN1/2B receptors in the influence of TMD mutations on Mg^{2+} block, and that mutation of GluN2B(W607) has complex effects on receptor function.

Title: Effects of lithium on NMDAR currents and intracellular calcium responses of rat cortical neurons

Authors: *D. A. SIBAROV, E. E. POGUZHELSKAYA, P. A. ABUSHIK, S. M. ANTONOV; Comparative Neurosci., Iephb RAS, Sankt-Peterburg, Russian Federation

Abstract: Lithium treatment is widely used in therapy of affective episodes in schizophrenia and bipolar disorder. However the complex mechanisms of lithium effects are still poorly understood. Previously we have shown that the substitution of lithium for sodium in the external solution reduces whole-cell neuronal currents mediated by N-Methyl-D-Aspartate receptors

(NMDARs), suggesting an acceleration of calcium-dependent NMDARs desensitization. In this study we analyze the relationship between the inhibition of sodium/calcium-exchanger by lithium and the value of calcium-dependent desensitization of NMDARs using the whole cell patch-clamp recordings and calcium imaging (Fluo-3AM) on rat cortical neurons *in vitro*. The partial substitution of lithium for extracellular sodium inhibited NMDA evoked steady-state currents in concentration-dependent manner. The most pronounced inhibition of currents was achieved during full substitution of lithium for sodium which reached the amplitude loss of about 75%. The IC_{50} for lithium effect was found to be of 25-30% of lithium substitution for sodium. The full substitution of lithium for sodium also decreased NMDA evoked calcium responses in neurons. Most likely the lithium effects on NMDARs are caused by an enforcement of calcium-dependent desensitization by the substrate inhibition of the sodium-calcium exchanger, that uncovers the sodium-calcium exchanger function in calcium clearance in the close proximity of intracellular domains of NMDARs. In addition self-effects of full substitution of lithium for sodium were found. In some neurons lithium induced gradual elevation of intracellular calcium and large inward whole-cell currents, which could be the result of an inhibition of sodium-dependent glutamate uptake, glutamate accumulation in synaptic clefts and additional calcium entry via ionotropic glutamate receptor channels.

Title: Modulation of NMDA receptors by TRPC6 and its function in synaptic plasticity

Authors: *H. SHEN[1], W. HU[2];
[1]Nantong Univ., Jiangsu, China; [2]Univ. of California, Davis, Davis, CA

Abstract: N-methyl-D-aspartate (NMDA) receptors play a key role in excitatory synaptic transmission, plasticity and neural development, and they also involved in neurodegenerative diseases and neuropsychiatric disorders. Therefore, regulation of the NMDA channel activity is critical for the physiological homeostasis and the pathological process of these diseases. Our work focuses on the modulation of NMDA receptors by pharmacological and endogenous

regulatory factor, for example, A. bidentata polypeptides (ABPP), an important constituent, which separated from the aqueous extract of A.bidentata Blume. Here, we reported that the canonical transient receptor potential channel 6 (TRPC6), a member of the TRPC family, can regulate the NMDA-induced current in primary cultured hippocampal neurons. Furthermore, TRPC6 can modulate the induction of the long term plasticity in CA3-CA1 synapses, and this function might involve in some mental diseases, such as depression and anxiety.

Title: NMDA receptor antagonist-induced gamma neuronal oscillations are augmented in the GluN-2C knockout mouse; implications for schizophrenia.

Authors: *Z. MAO[1], Y. ZHANG[2], K. SAPKOTA[3], H. ALSAAD[3], S. DRAVID[4], D. MONAGHAN[3];
[1]Dept. of Pharmaceut. Sci., [2]Pharm. Practice, [3]Dept. of Pharmacol. and Exptl. Neurosci., Univ. of Nebraska Med. Ctr., Omaha, NE; [4]Dept. of Pharmacol., Creighton Univ., Omaha, NE

Abstract: NMDA receptors appear to be involved in many neuropsychiatric diseases such as schizophrenia, autism spectrum disorder, bipolar disorder, and others. Their role in these disorders may be through causing a disruption in neuronal oscillations. Human studies have demonstrated increased basal gamma oscillatory activity in schizophrenics and reduced evoked oscillations. Similarly, NMDAR antagonists such as ketamine, and PCP augment basal neuronal oscillations in the gamma (and other frequency bands) while also mimicking the behavioral symptoms of schizophrenia. To identify the receptor subunits responsible for NMDAR antagonist modulation of neuronal oscillations, we examined the ability of the commonly used NMDAR antagonists (ketamine, PCP, and memantine) to stimulate neuronal oscillations in wildtype (WT) and GluN2C-knockout (GluN2C-KO) mice. Basal neuronal oscillations were measured by electrocorticography (ECoG) before and after drug administration in WT and GluN2C-KO mice. Frequency power spectrum analysis indicated that each of these NMDAR antagonists induced a larger increase in the gamma band's (30-100 Hz) oscillatory power in the cerebral cortex in GluN2C-KO mice compare to WT mice. Examination of 10 Hz bands

indicated that ketamine-enhanced power was significantly larger in the GluN2C-KO mice compared to WT mice in the 30-40, 40-50, and 50-60 Hz frequency bands. These results contrast with our recent findings that ketamine is not able to augment gamma oscillations in the GluN2D-KO mouse (Sapkota et al., JPET 356:702-711, 2016). Hence, GluN2C and GluN2D subunits appear to have significant and distinct contributions to the modulation of gamma oscillations by NMDA receptors.

Title: Psd95 deficiency alters nmda and ampa receptor expression and function during development in the prefrontal cortex

Authors: *A. COLEY[1], W.-J. GAO[2];
[1]Dept. of Neurobio. and Anat., Drexel Univ. Col. of Med., Philadelphia, PA; [2]Drexel Univ., Philadelphia, PA

Abstract: Postsynaptic density protein– 95 (PSD-95) is a major regulator in the maturation of excitatory synapses by interacting and trafficking N-methyl-D-aspartic acid receptors (NMDAR's) and α-amino-3-hydroxy-5-methyl-4-isox-azoleproprionic acid receptors (AMPAR's) to the postsynaptic membrane of the dendritic spine. PSD-95 and NMDA dysfunction have been associated with cognitive and learning deficits connected to psychiatric disorders such as autism and schizophrenia. Using a PSD-95 knockout mouse model (PSD-95$^{-/-}$), we examined how PSD-95 deficiency affects NMDAR and AMPAR expression and function in the dorsomedial prefrontal cortex (dmPFC) at postnatal days 21, 35 and 70, i.e., juvenile, adolescent and adult periods, respectively. We found significant increases in total protein levels of NMDAR subunits NR1, NR2B and NR3A, accompanied with a trending decrease in AMPAR subunit GluR1 during adolescence. However, no significant changes in protein levels were observed during juvenile and adult time points, indicating that the adolescence age range is a critical period at which PSD-95 influences NMDAR and AMPAR expression levels in the dmPFC. Whole-cell patch clamp recordings of NMDA- and AMPA-mediated currents were also

performed from the layer 5 pyramidal neurons of the dmPFC and NMDA/AMPA ratios were calculated. We found a significant increase in NMDA-mediated current and a decrease in AMPA-meditated current in PSD-95$^{-/-}$ mice during adolescence. In addition, PSD-95$^{-/-}$ mice show a decrease in NMDAR-mediated current decay compared to control mice, which is indicative of the significant increase in NR3A protein expression levels. Our data suggest that the increase in NMDAR expression and function and a decrease in AMPAR are representative of a a potential increase in "silent synapses" or disrupted synaptic formation. This study will be used to describe the importance of PSD-95 during dendritic spine development in the dmPFC and its potential association in the pathogenesis of cognitive and learning deficits in autism and/or schizophrenia.

Abstract: Dysfunction of glutamatergic neurotransmission is thought to underlie a variety of psychiatric disorders such as schizophrenia and attention-deficit hyperactivity disorder. Since the α-amino-3-hydroxyl-5-methyl-4-isoxazole propionate (AMPA) subtype of ionotropic glutamate receptors mediate the majority of fast excitatory neurotransmission within the CNS, then modulation of AMPA receptors (AMPAR) is an attractive potential therapeutic approach. More specifically, compounds that are AMPAR positive allosteric modulators (PAMs) have been designed to enhance AMPAR function in disorders associated with glutamatergic hypofunction. Of these compounds, arguably the best known are the AMPAkine class of compounds, typified by CX516, CX691 and CX717. An issue with compounds that amplify the function of AMPARs is the potential for hyperexcitability, resulting in a proconvulsant or convulsant liability. We

have recently identified a novel class of compounds that are AMPAR PAMs that are devoid of any proconvulsant liability. Hence, these compounds potentiate AMPA currents in a human recombinant AMPAR (GluA2)-expressing cell line and rat primary neurons but are not proconvulsant in mouse hippocampal brain slices optimised to detect proconvulsant activity by reducing the extracellular Mg^{2+} concentration. Moreover, *in vivo* these compounds do not lower the seizure threshold, and are therefore not proconvulsant, in a rat maximal electroshock seizure threshold assay at doses of 300 mg/kg p.o. These compounds also enhance AMPA-mediated currents in a rat *in vivo* electrophysiology assay and enhance cognitive performance in the rat novel object recognition assay. Three of these compounds have been selected for further development and are currently undergoing preclinical safety and toxicity assays ready for first-in-human testing.

Abstract: Glutamate and its receptors have been of longstanding interest since dysfunction of the glutamatergic signalling pathway has been associated with the pathophysiology of several psychiatric and neurological disorders. The research on AMPA receptor positive allosteric modulators offers opportunities to modulate fast excitatory synaptic transmission and thus identify potential therapeutic agents for a range of disorders. The field of AMPAR modulators continues to be a dynamic area of drug discovery with a pronounced diversification of the chemotypes explored in recent years, however no molecules have yet progressed beyond preliminary Phase 2 evaluation.We report the full pharmacological characterisation and

translational characterisation of [*N*-[(2*S*)-5-(6-fluoro-3-pyridinyl)-2,3-dihydro 1*H*-inden-2-yl] -2-propanesulfonamide] a molecule which is a novel, potent and selective AMPA receptor positive allosteric modulator, currently in Phase 1 investigation. The supporting data to be presented demonstrate that the molecule is a positive allosteric modulator of the AMPA receptor and also that it was selective versus NMDA and kainate glutamate receptors. This potentiation was independent of subunit or orthologue composition in recombinant receptors, and was also demonstrated in rat native receptors. In vivo, the molecule was able to reverse a time delay-induced deficit in novel object recognition in rats after both acute and sub-chronic dosing. Sub-chronic dosing reduced the minimum effective dose from 0.3 mg/kg to 0.03 mg/kg. Efficacy was observed in additional cognition models. In side-effect profiling studies, there were no significant changes in the maximal electroshock threshold test at doses below 10 mg/kg. In conclusion, [*N*-[(2*S*)-5-(6-fluoro-3-pyridinyl)-2,3-dihydro 1*H*-inden-2-yl] -2-propanesulfonamide] is a potent and selective AMPAR modulator which exhibits cognition enhancing properties in several rat behavioural models superior to other molecules which have previously entered clinical evaluation and with a safety profile supportive of progression to clinical testing.

Title: Identification and characterization of the binding pocket for negative allosteric modulators in AMPA receptors

Authors: *C. STENUM-BERG, C. L. THISTED, S. C. ABIEGA, A. S. KRISTENSEN; Dept. of Drug Design and Pharmacol., Univ. of Copenhagen, Kobenhavn O, Denmark

Abstract: AMPA receptors (AMPARs) are present throughout the CNS and mediate the majority of fast excitatory neurotransmission, and are involved in most brain functions. Abnormal AMPAR activity is implicated in neurological CNS diseases such as Alzheimer's, Parkinson's, epilepsy and psychiatric diseases. Recently, the first AMPAR-selective drug was approved in the form of perampanel for treatment of epilepsy. Perampanel belongs to the class of negative allosteric modulators (NAMs), inhibiting AMPAR activity via a non-competitive

mechanism. However, little is known about the location and structure of binding sites for perampanel or other prototypical AMPAR NAMs such as GYKI-53655 and CP-465,022. Identifying NAM binding sites and establishing NAM binding modes is prerequisite to understanding the molecular mechanism that underlies negative allosteric modulation of AMPAR function and is important for future development of other NAMs.
This project aims to characterize the binding sites and binding modes of perampanel and other NAMs. AMPARs are tetrameric assemblies of structurally closely related GluA1 to GluA4 subunits. The subunit architecture is highly modular with two large extracellular domains - the amino-terminal domain (ATD) and the ligand-binding domain (LBD) - that connect via three flexible linkers (denoted S1-M1, S2-M3, and S2-M4) to a transmembrane domain (TMD). Previous work has identified regions within the linker regions to harbor specific residues that can control NAM functional potency (Balannik et al., 2005, Neuron). To further identify specific amino acid residues in these regions that participate in NAM interaction, mutational scanning was performed of the S1-M1 and S2-M4 linker regions. 43 point mutants were functionally and pharmacologically characterized using an intracellular calcium imaging assay of AMPAR activity in HEK293 cells and an enzyme-based surface expression assay. For the 32 mutants with intact receptor function, concentration-response curves were constructed for four prototypical NAMs, including perampanel, to identify mutant effects on NAM inhibitory potency (IC50). Mutations at 12 positions were found to induce a >5-fold change in IC50 of one or more NAMs. Mapping of these amino acid positions in the crystal structure of the GluA2 AMPAR (Sobolevsky et al., 2009, Nature) identify two major areas to be involved in NAM function. The key mutants for which NAM inhibition was altered by at least five-fold in the calcium imaging assay are being further characterized by two-electrode voltage clamp electrophysiology.The mutational dataset will be used to guide molecular modeling studies of NAM binding modes to the receptor.

Abstract: AMPA-type glutamate receptors (AMPARs), key players in excitatory neuro-transmission in the brain, are macromolecular complexes whose properties and cellular functions are determined by the co-assembled constituents of their proteome. Here we identify AMPAR assemblies containing FRRS1l/C9orf4 that are restricted to the endoplasmic reticulum and lack the core-subunits typical of AMPARs in the plasma membrane. Bi-allelic mutations in the human FRRS1l gene cause severe intellectual disability, cognitive impairment, speech delay and epileptic activity. Virus-directed deletion or overexpression of FRRS1l in adult rats alters the number of surface AMPARs in individual synapses resulting in decreased or increased amplitudes of the excitatory postsynaptic currents (EPSC) without effects on their time courses. Our results provide insight into the early biogenesis of AMPARs and demonstrate its impact on synaptic transmission and brain function.

Title: Identification of a novel protein that regulates endosome pH, AMPAR trafficking and synaptic function

Authors: *A. J. KALLARACKAL[1], J. MELLEM[2], D. M. MADSEN[2], V. MARICQ[2];
[1]Dept Biol., [2]Biol., Univ. of Utah, Salt Lake City, UT

Abstract: Dynamic regulation of glutamatergic AMPA receptors is crucial for synaptic function, behavior and cognition. We recently demonstrated that AMPARs are actively transported to synapses along microtubules via kinesin motors and that this transport is regulated by CaMKII. We now address how AMPAR exocytosis and endocytosis is regulated following delivery. In a forward genetic screen, we identified a novel mutant that increased the pH of AMPAR transport vesicles. Through whole genome sequencing we identified that the phenotype was due to a point mutation in a relatively uncharacterized gene that has been implicated in neurodegenerative disease. Furthermore, we found that this alkalized pH is mediated by a sodium-proton exchanger. In both mutants, we found defects in synaptic function that are a consequence of altered exocytosis. These findings provide new mechanistic insights into glutamatergic signaling and the consequences of altered regulation of intracellular pH.

Title: Mechanisms underlying slow AMPA-receptor mediated current at mossy fiber-unipolar brush cell synapse

Authors: H.-W. LU[1], *T. S. BALMER[2], G. E. ROMERO[3], L. O. TRUSSELL[2,1];
[1]Vollum Inst., [2]Oregon Hearing Res. Ctr., [3]Physiol. & Pharmacol., Oregon Hlth. and Sci. Univ., Portland, OR

Abstract: Most AMPA-receptor (AMPAR) mediated EPSCs in the nervous system last only a few milliseconds. However, at mossy fiber-unipolar brush cell (UBC) synapses in the cerebellum, a slow AMPAR-mediated EPSC lasting for hundreds of milliseconds emerges after fast EPSCs end, leading to a prolonged depolarization. The slow current has been hypothesized to reflect the bell-shaped steady-state dose-response for desensitized AMPA receptors produced by slowly declining [glutamate] in the synaptic cleft. Here we provide evidence for this process using glutamate uncaging, synaptic stimulation, rapid glutamate application, and γ-2 TARP mutant mice (stargazer). Recordings were made from UBCs in WT or stargazer mouse brain slices containing cerebellar lobe X. A 2-ms uncaging of 1 mM MNI-glutamate at the synapse generated a fast-then-slow current similar to that evoked by synaptic stimulation. When the same uncaging pulse was delivered 15 ms after synaptic stimulation, the peak of the fast uncaging current was attenuated by 89 ± 1 % (n = 5), showing that AMPA receptors are greatly desensitized by synaptically released glutamate. Desensitization of the peak response recovered during the course of slow current phase with a time constant of ~296 ± 31 ms (n = 5), indicating that [glutamate] was slowly decreasing in the synaptic cleft. Similar desensitization was also observed by paired-uncaging pulses (recovery time constant: 465 ± 55 ms, n = 6). Application of 5% dextran to the bath reduced the decay of the slow EPSC (553 ± 140 to 830 ± 241 ms, n = 4), further supporting the role of slow glutamate diffusion in this process. Rapid-application of different concentrations of glutamate onto dissociated UBCs showed that the steady-state response peaks at ~32 μM and decreases as [glutamate] increases (response at 1 mM vs 32 μM: 70 ± 6 %, n = 11), suggesting that the cleft [glutamate] at the peak of the slow EPSC is around 32 μM. This bell-shaped dose response curve was absent in dissociated UBCs from stargazer mice (response at 1 mM vs 32 μM: 95 ± 3 %, n = 9), and the slow EPSC evoked by synaptic stimulation was significantly smaller compared with wild-types (5.2 ± 0.4 vs 13.5 ± 1.5 pA, n = 13 and 17, respectively), suggesting that γ-2 TARPs enhance the steady-state response at the mid-micromolar range. These effects could be reproduced using a kinetic model which stabilized open states of less-than-fully occupied AMPA receptors during slow transmitter transients. Taken together, we provide the evidence that the slow EPSC at mossy fiber-UBC synapse is due to slow diffusion of glutamate in the synaptic cleft, that it is mediated by desensitized AMPARs, and that TARPs regulate this process.

Title: Claudins: An unexpected source for more tetraspanning proteins acting as transmembrane AMPA receptor modulatory proteins

Authors: S. HAERING[1], S. BHATTACHARYA[2], M. ASLAM[3], T. STRASDEIT[4], J. VON ENGELHARDT[3], S. F. TRAYNELIS[2], *M. HOLLMANN[5,4];

Biochem. I - Receptor Biochem., [5]Ruhr Univ. Bochum, Bochum, Germany

Abstract: The ionotropic glutamate receptors (iGluRs) are known to play a major role in excitatory signal transmission in the central nervous system. Although these receptors are able to function on their own, many interacting and modulating auxiliary subunits have been found. Some of them influence biophysical properties of iGluRs while others modulate the trafficking of the receptors to the plasma membrane. The most commonly known proteins are the transmembrane AMPA receptor regulatory proteins (TARPs), cornichon homologs (CNIH), neuropilin- and tolloid-like proteins (NETOs), cysteine-knot AMPAR modulating protein (CKAMP44), SynDigI, suppressor of lurcher-1 (SOL-1), and GSG1L.
We recently identified another class of proteins as possible AMPA receptor auxiliary subunits, the claudins. While generally known as tight junction proteins that seal passageways within and in between plasmamembranes, claudins show high structure and sequence homology with the TARP proteins. Of the 22-24 different claudin genes identified in rat, mouse, and humans, few have been functionally characterized. We show in two different expression systems, *Xenopus* oocytes and HEK-293 cells, that certain claudins, claudin-20 and claudin-24 in particular, potentiate the current amplitude and modulate the desensitization of certain AMPA receptors. The electrophysiological properties of other iGluR subtypes are not affected, and other claudins do not show this modulatory action. We identified unexpected amplitude potentiations at first in the oocyte system on GluA1 and GluA2 receptors, with effects being more pronounced with flip than with flop splice variants and with R than with Q editing variants. It still remains to be tested whether this exquisitely variant-specific effect, which is reminiscent of the TARP γ5, will be similarly variant-specific when tested in HEK cells.
We further show that both claudin-20 and claudin-24 are expressed in the brain, particularly in

the granule cell layers of the cerebellum and the olfactory bulb, and claudin-24 in addition to a lesser degree in the principal cells of the hippocampus. Finally, we used FRET after acceptor bleaching to demonstrate that claudin-20 interacts directly with GluA1.

Title: Secreted amyloid precursor protein-alpha regulates synthesis of the AMPA receptor subunit GluA1

Authors: ***M. K. ELDER**[1], K. PEPPERCORN[2], S. TOM DIECK[4], L. KOCHEN[4], E. SCHUMAN[4], W. TATE[2], C. ABRAHAM[3], J. WILLIAMS[1];

Abstract: The amyloid precursor protein, best known as the precursor molecule to toxic beta amyloid, can also liberate a neuroprotective secreted fragment called secreted amyloid precursor protein-alpha (sAPPα). This fragment, derived from proteolysis by α-secretase enhances long-term potentiation (LTP) and spatial memory. The mechanism/s by which sAPPα facilitates these functions are as yet unknown. However, previously we have shown that sAPPα enhances synaptic protein synthesis, and as de novo protein synthesis is a requirement for persistence of both memory and LTP, we hypothesized that sAPPα may upregulate the synthesis of key proteins involved in these processes. As regulation of the ionotropic α-amino-3-hydroxy-5-

methyl-4-isoxazolepropionic acid (AMPA)-subtype of glutamate receptors is critical for LTP, in the current study we investigated the effect of sAPPα on the synthesis of the GluA1 and GluA2 subunits of this receptor. Following 2 h incubation of hippocampal neuronal primary cultures with sAPPα (1 nM), fluorescent non-canonical amino acid tagging with proximity ligation assays (PLA-FUNCAT) was used to label newly synthesized GluA1 or GluA2 subunits. Here, a methionine analogue bound to an azide group (azidohomoalanine, AHA) was co-incubated with sAPPα and incorporated into newly synthesized proteins in methionine-free media. Using click chemistry, a biotin-bound alkyne was linked to the AHA incorporated in new proteins, and this complex was recognized with high specificity using antibodies and PLA probes.
Using this technique, we revealed a cell-wide increase in GluA1 synthesis in response to sAPPα ($p < 0.0005$, Kruskal Wallis test), with two-fold more GluA1 visible in the dendritic compartment following treatment ($p < 0.05$). No effect was observed on the level of GluA2 synthesis in response to sAPPα. Together, these results reveal a possible mechanism of action, where sAPPα mediates an increase in GluA1 synthesis, enhancing availability of the subunit and therefore facilitating LTP and memory formation.

Title: Extensive phosphorylation of AMPA receptors in neurons

Authors: ***N. K. HUSSAIN SHULER**, G. H. DIERING, S. HEO, B. LIU, R. L. HUGANIR; Dept. of Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Changes in the synaptic targeting of AMPA receptors (AMPARs) is a fundamental mechanism controlling synaptic strength during long-term potentiation/depression and homeostatic scaling. AMPAR trafficking is controlled by protein-protein interactions as well as post-translational modifications. Phosphorylation of the GluA1 AMPAR subunit at S845 and

S831 play especially important roles during synaptic plasticity. Recent controversy has emerged regarding the extent to which GluA1 phosphorylation may contribute to synaptic plasticity. Here we used a variety of methods to measure the population of phosphorylated GluA1-containing AMPARs in cultured primary neurons and mouse forebrain. We demonstrate that phosphorylated GluA1 represents large fractions of the total population under basal and stimulated conditions in vitro and in vivo. Our results support the large body of research indicating a prominent role of GluA1 phosphorylation in synaptic plasticity.

Title: The auxiliary subunit C9orf4 (FRRS1l) slows AMPAR recovery from desensitization

Authors: *S. PEARCE, M. FARRANT, S. G. CULL-CANDY;
NPP, Univ. Col. London, London, United Kingdom

Abstract: AMPA-type glutamate receptors (AMPARs) mediate the majority of fast excitatory neurotransmission in the mammalian CNS. These receptors are associated with various auxiliary proteins that affect their properties. Transmembrane AMPAR regulatory proteins (TARPs), the first identified AMPAR auxiliary subunits, have been shown to influence receptor trafficking, kinetics and pharmacology [1]. Additional auxiliary subunits have been identified, including the cornichon homologues CNIH-2 and CNIH-3, and the proteins CKAMP-44 and GSG1L, all of which individually influence AMPAR properties [2-5]. One interacting protein for which no functional effects have yet been described is the transmembrane protein ‘chromosome 9 open reading frame 4’ (C9orf4) (also known as ferric-chelate reductase 1-like protein; FRRS1l) [5]. Using patch-clamp recording and rapid glutamate application to excised patches, we have investigated the effects of C9orf4 co-expression on homomeric (GluA1) and heteromeric (GluA1/A2) AMPARs in tsA201 cells. C9orf4 slowed recovery from desensitization (induced by

100 ms application of 10 mM glutamate) without affecting other AMPAR properties. When the prototypical TARP stargazin (γ-2) was co-expressed, the effect of C9orf4 was lost and receptor properties resembled those of AMPARs associated with γ-2 alone. In cultured hippocampal neurons, overexpression of C9orf4 had no effect on mEPSC amplitude or frequency, suggesting either that it does not associate with native TARP-coupled receptors, does not alter their functional properties, or that C9orf4-associated AMPARs do not reach the synapse. Further experiments are required to determine the mechanism by which C9orf4 slows AMPAR recovery from desensitization, and its functional significance. 1. Title: Characterization of AMPAR auxiliary subunit GSG1L expression pattern and function using transgenic model systems

Authors: *A. KAMALOVA[1], E. ZAIKA[1], K. FUTAI[2], E. DELPIRE[1], T. NAKAGAWA[1]; [1]Mol. Physiol. and Biophysics, Vanderbilt Univ., Nashville, TN; [2]Dept. of Psychiatry, Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract: AMPA receptors (AMPAR) are the predominant excitatory neurotransmitter receptors that mediate fast excitatory synaptic transmission in the brain. The density of AMPARs at the synapse is postulated to underlie a subset of synaptic plasticity. AMPAR auxiliary subunits are transmembrane regulatory proteins that selectively associate with AMPARs affecting various aspects of AMPAR life cycle from early trafficking to gating kinetics. GSG1L is a newly identified auxiliary subunit identified in our laboratory with unique AMPAR regulatory properties. GSG1L slows the rate of desensitization, similar to what was observed for the canonical transmembrane AMPAR regulatory proteins (TARPs). However, while TARPs speed the recovery from desensitization, GSG1L slows this process in heterologous systems.

Furthermore, a recent study demonstrated that GSG1L reduces the average single-channel conductance and enhances polyamine block of calcium permeable AMPARs. It is unknown, however, which brain regions and subset of neurons express GSG1L. To address this, we conducted histological analysis on a transgenic rat that expresses a lacZ reporter under endogenous GSG1L promoter. In this transgenic rat, a lacZ reporter disrupts the GSG1L gene by interrupting its normal RNA splicing event, producing a GSG1L KO. Using lacZ localization, we deduced the spatio-temporal expression pattern of GSG1L during postnatal development, which was revealed to be highly dynamic. While GSG1L expression was undetectable in hippocampus during early postnatal development, it increased in DG and CA3 regions in older animals. Expression was also high in L2/3 cortical neurons. The LacZ expression pattern in heterozygotes, which express half dose of GSG1L, was comparable to that of the homozygotes, which express negligible amount of GSG1L. The expression pattern deduced from lacZ staining is consistent with in situ hybridization data from Allen Brain Atlas. However, the current results extend our knowledge of GSG1L distribution by providing more detailed spatiotemporal analysis. In order to characterize GSG1L function in synapses, we then generated GSG1L KO mouse model owing to availability of homogenous genetic backgrounds and genetic tools. The phenotype is currently being characterized and progress will be presented at the meeting.

Title: Using high throughput screening methods to identify small molecule modulators that specifically target the GluA2-auxiliary subunit complex

Authors: *C. AZUMAYA[1], E. DAYS[2], P. VINSON[2], S. STAUFFER[3], G. SULIKOWSKI[4], D. WEAVER[3], T. NAKAGAWA[5];
[2]Vanderbilt Inst. of Chem. Biol., [3]Pharmacol., [4]Chem., [5]Mol. Physiol. and Biophysics, [1]Vanderbilt Univ., Nashville, TN

Abstract: AMPA receptors (AMPAR) are ligand gated ion channels that are critical to maintain normal synaptic plasticity. Because of their integral role in fast excitatory neurotransmission, AMPA receptor dysfunction is implicated in a variety of cognitive diseases ranging from developmental to degenerative. Attempting to potentiate or depress AMPAR activity is an inherently difficult balancing act between effective treatment and debilitating side effects. A newly explored avenue for increasing our ability to target subsets of AMPAR in the central nervous system is to identify compounds that target specific AMPAR-auxiliary subunit complexes. Here we report a high throughput screening-based pipeline that is able to identify compounds targeted to certain GluA2-auxiliary subunit combinations, specifically, GluA2-CNIH3 and GluA2-stargazin. These compounds will build upon the growing library of AMPAR-auxiliary subunit specific modulators which have so far all been targeted to TARP-8. Our screening protocol begins with a cell-based assay that utilizes a voltage sensing dye to identify changes in membrane potential of HEK cells co-expressing GluA2 and an auxiliary subunit. This primary screen was followed by a set of counterscreens to remove compounds working through undesired mechanisms. Our workflow was able to narrow an initial library of 40,000 compounds down to 54 hits that are specific for GluA2-stargazin or GluA2-CNIH3 expressing cell lines for further characterization using electrophysiology, fluorescence-based calcium flux assay, and co-immunoprecipitation assay. Candidate compounds from the initial screen have been identified as negative (NAM) and positive (PAM) allosteric modulators specific to either stargazin or CNIH3. Candidate compounds that affect both auxiliary subunit containing complexes, but not GluA2 alone, were also identified. Progress on further verification of these candidate compounds is underway. Our pipeline is a feasible way to identify compounds that are specific to many different iGluR-auxiliary subunit combinations, which could prove important to specific targeting of auxiliary subunit containing complexes in the lab and clinic. Differential expression patterns for auxiliary subunits throughout the central nervous system presents a rational approach to specifically target AMPARs in certain regions of the brain to decrease the potential of on-target side effects.

Title: Decreased palmitoylation of PSD-95 contributes to src mediated NMDA receptor hypoactivity in schizophrenia

Authors: *A. BANERJEE[1], A. SENGAR[2], J. KIM[3], R. RAY[4], K. BORGMANN-WINTER[5], M. SALTER[6], C.-G. HAHN[3];
[1]Dept. of Psychiatry, Univ. Ctr. and department of Physiol., Sick Kids and Univ. of Toronto, Toronto, ON, Canada

Abstract: Decreased GluN2 tyrosine phosphorylation and Src kinase hypoactivity are molecular signatures of disrupted NMDA receptor (NR) signaling in schizophrenia. Src hypoactivity can be traced to various molecular alterations in the DLPFC of schizophrenia subjects, one of which is through PSD-95. Here we report that increased PSD-95 within NR complex in schizophrenia results from its altered palmitoylation and trafficking into the PSD which in turn may reduce src activity in NR complex.
DLPFC tissues obtained from 15 pairs of SCZ and healthy subjects (UPenn SCZ brain bank) were subjected to subcellular fractionation, western blotting, immunoprecipitation, acyl biotin exchange assay for detecting palmitoylation, src activity assay with the PSD-95 inhibitory peptide (SAPIP), qPCR, RNA seq. SAPIP increased src activity ($p \leq 0.020$) in synaptic membrane (P2) by reducing interaction between src and PSD-95. PSD-95 protein was increased in ER/Golgi enriched fractions (P3) in schizophrenia ($p \leq 0.001$). C2'-GluN1: PSD-95 association, which increases membrane trafficking of PSD-95, was increased ($p \leq 0.004$) in the PSD in SCZ. Palmitoylation of PSD-95, that increases membrane transport of PSD-95 was decreased in both P3 ($p \leq 0.027$, $t=2.489$ $df=13$) and P2 ($p \leq 0.005$). RNA seq analysis on PSD-95 specific palmitoyltransferase ZDHHC 2, 7, 8 and 15 showed no significant changes in expression in SCZ whereas ZDHHC 3 transcript was decreased in SCZ ($p \leq 0.0006$) by ~10%. Our findings lead us to propose a model in which in SCZ decreased membrane trafficking of PSD-95 due to decreased palmitoylation leads to an alternate path of membrane transport via C2'-GluN1 and inhibition of src activity specifically within NR complexes.

Title: State-dependence alone does not provide a sufficient CNS margin with an orally efficacious Cav2 selective small molecule

Authors: *K. S. RATLIFF[1], K. KNOPP[2], J. SCHKERYANTZ[2], B. T. PRIEST[2], M. CLARK[2], R. CERNE[2], M. WAKULCHIK[2], B. HEINZ[2], M. WALKER[2], A. VANDERGRIFF[2], X. HUANG[2], M. J. VALLI[2], W. J. PORTER[2], J. K. REEL[2], D. LUFFER-ATLAS[2], T. JONES[2], R. M. A. SIMMONS[2], B. FORSTER[2], W. GUO[2], B. ADAMS[2], L. YANG[2], J. S. MCDERMOTT[2]; [1]Neurosci. Discovery, Indianapolis, IN; [2]Eli Lilly & Co., Indianapolis, IN

Abstract: The N-type voltage gated calcium channel, Cav2.2, has long been a target of interest for chronic pain drug discovery. This has been based principally on the clinical efficacy observed with ziconotide (ω-conotoxin-MVIIA), a potent and selective Cav2.2 inhibitor derived from the venom of a cone snail. Unfortunately, the clinical utility of ziconotide has been limited by both its intrathecal route of administration as well as a very narrow therapeutic margin. Typical side effects include CNS and baroreceptor deficits that manifest at, or just above therapeutic drug concentrations. This narrow therapeutic margin may be the result of the state-independent mechanism of action of ziconotide. The addition of state-dependence in a Cav2.2 directed therapy would selectively target more depolarized and/or rapidly firing nociceptors, and spare the more hyperpolarized Cav2.2 expressing neurons, perhaps diminishing some of the adverse effects. However, despite over a decade of small molecule drug discovery efforts, clinical proof of concept for this hypothesis has been elusive. In addition, ligands disclosed to date possess the desired state-dependence, but not the selectivity of ziconotide, as they are typically selective over other Cav family members, but equipotent for Cav2.1, 2.2, and 2.3. There is a single report showing a 20-fold preclinical CNS margin with a potent and state-dependent Cav2 selective small molecule, and while this is an improvement over ziconotide, this compound has apparently not progressed into clinical testing. Here we describe a potent and state-dependent Cav2 selective small molecule, 3302917, that is efficacious in multiple preclinical in vivo pain assays. The compound also achieved exposures in a rodent toxicity study sufficient for a 10-fold CNS margin determination, with ataxias being the primary observation. 3302917 also showed efficacy in a formalin assay in Cav2.2$^{-/-}$mice, and while this result would typically be interpreted as evidence of off-target effects, we believe that both the ataxias observed in the toxicity study and the efficacy in the Cav2.2 null mice provide evidence of Cav2.1 inhibition. Cav2.1 is highly expressed in the cerebellum and loss of function mutations in humans are linked to ataxias. In addition, Cav2.1 selective toxins have shown efficacy in the formalin model. While efficacious in multiple pain assays, 3302917 did not have the desired CNS margins to allow further development. We propose that future drug discovery efforts targeting Cav2.2 should incorporate not only a state-dependent mechanism of action, but also some degree of Cav2.1 selectivity.

Title: L-type voltage gated calcium channels functionally couple with IKCa channels in CA1 pyramidal cells to generate the slow afterhyperpolarization

Authors: *G. SAHU, J. MICLAT, H. ASMARA, G. W. ZAMPONI, R. W. TURNER; Hotchkiss Brain Inst., Univ. of Calgary, Calgary, AB, Canada

Abstract: Calcium activated potassium (KCa) channels control the frequency and pattern of spike discharge in hippocampal pyramidal neurons. The intermediate conductance KCa (IKCa) channel (KCa3.1) was recently reported to contribute to generation of the slow afterhyperpolarization (sAHP) (King et al. 2015). Voltage-gated calcium channels of the L-type (CaV1 family) have been reported to act as a primary calcium source for the sAHP, but these tests relied on dihydropyridine blockers that also block IKCa. The current study examined the ability for CaV1.2 or CaV1.3 channels to activate IKCa to contribute to the sAHP. Coexpression of CaV1 and KCa3.1 cDNA in tsA-201 cells revealed that either CaV1.2 or

CaV1.3 is sufficient to activate IKCa channels, with a close relationship between voltage-dependent activation of CaV1 currents and the magnitude of IKCa. Moreover, step commands that maximally activated CaV1 channel isoforms for 5-150 msec produced a graded activation of IKCa that lasted 1-5 sec, effectively recreating an IsAHP. Recordings from CA1 pyramidal cells in vitro in the presence of blockers against all CaV channel isoforms (except L-type), SK, BK, and Kv7 channels confirmed the activation of IsAHP that was sensitive to 1 μM TRAM-34, a selective IKCa blocker. Similarly, application of 500 nM isradipine determined in tsA-201 cells to block Cav1 but not KCa3.1 channels reduced IsAHP area and spike accommodation in CA1 pyramidal cells. Moreover, CaV1.3 but not CaV1.2 channels exhibited calcium-dependent facilitation when coexpressed with the scaffolding protein densin and CaMKII and activated with the 50 Hz protocol relevant to generating IsAHP. Further, siRNAs against densin reduced IsAHP area and calcium-dependent facilitation in cultured hippocampal pyramidal neurons. The CaV1-mediated activation of IKCa channels in pyramidal cells was blocked by internal 5 mM EGTA, suggesting a microdomain-based interaction.
The results suggest that L-type calcium channel isoforms, and more specifically CaV1.3, are sufficient to activate IKCa channels in a manner consistent with the sAHP in CA1 pyramidal neurons.

Title: The $5HT_{2C}$ receptor decreases seizure susceptibility in the dorsal subiculum by inhibiting Ca_V3 ion channels

Authors: *A. PETERSEN[1], C. S. JENSEN[1], V. CRÉPEL[2], M. FALKERSLEV[1], J.-F. PERRIER[1];
[1]Copenhagen Univ., Copenhagen N, Denmark; [2]INSERM U901, INMED, Marseille, France

Abstract: The subiculum is the major output region of the hippocampal network. It receives inputs from CA1 and entorhinal cortex and sends projections to several cortical and subcortical areas. Under pathological conditions, epileptic seizures start from the subiculum before spreading to the temporal lobe. Since serotonin (5-HT) was reported to have an antiepileptic effect, we investigated if and how it modulates the activity of principal cells from the subiculum. In two *in vitro* rodent models for epilepsy, we found that 5-HT inhibits subicular seizures. To understand the underlying mechanism, we recorded the electrical activity of subicular pyramidal neurons with the whole-cell patch clamp technique in a slice preparation from the hippocampus of mice. In agreement with previous observations, we found that subicular neurons fired action potentials in bursts triggered by a low threshold calcium spike. Focal release of 5-HT induced by pressure or microiontophoresis inhibited the burst firing. The calcium current responsible for burst firing was recorded in voltage-clamp mode after blocking Na^+ and K^+ voltage gated ion channels. A puff application of 5-HT decreased the amplitude of a low-threshold transient inward current sensitive to mibefradil. These results suggest that 5-HT inhibits a current mediated by T-type (Ca_V3) Ca^{2+} channels. To corroborate our findings, we monitored the variations in Ca^{2+} concentration by loading recorded cells with the Ca^{2+} indicator FURA-2. We observed that burst firing evoked by depolarizing current pulses induced an increase in Ca^{2+} concentration. When 5-HT was puff-applied, the Ca^{2+} signal was attenuated in all compartments of the neuron (AIS, soma, dendrites). Puffing a $5\text{-}HT_{2C}$ agonist (WAY 629 or WAY161503) had the same inhibitory effect on the burst firing and Ca^{2+} current. Using immunohistochemistry, we found that $5\text{-}HT_{2C}$ receptors are expressed in the dendrites of subicular pyramidal neurons in the vicinity of $Ca_V3.1$ and $Ca_V3.3$. When tested on in vitro model for epilepsy, $5\text{-}HT_{2C}$ agonists had an inhibitory effect comparable to 5-HT. Finally, we tested if the inhibitory effect could be obtained by synaptic release. Using a mouse expressing channelrhodopsin under the promoter controlling tryptophan hydroxylase 2, we evoked synaptic release by applying blue light in in the subiculum. It consistently inhibited the bursting of principal cells.
Our data suggest that the anti-epileptic effect of 5-HT in subiculum is mediated by 5-HT2c receptors, which in turn inhibit the T-type calcium channels responsible for the burst firing of principal cells.

Title: Crosstalk between $InsP_3R$ and TRPV4 in Ca^{2+} microdomains contributes to paclitaxel-induced neurotoxicity

Authors: *W. BOEHMERLE, P. HUEHNCHEN, C. HARMS, M. ENDRES;
Charite Universitaetsmedizin Berlin, Berlin, Germany

Abstract: Neurotoxic phenomena are among the most common side effects of cytostatic chemotherapy and affect a large number of patients. Paclitaxel is a common antineoplastic drug which frequently causes length dependent sensory polyneuropathy. Increasing evidence suggests, that altered intracellular calcium (Ca2+) signals play an important role in the pathogenesis of paclitaxel-induced peripheral neuropathy. In the present study, we examined in cultivated dorsal root ganglion cells the interplay between Ca2+ release channels in the endoplasmic reticulum (ER) and Ca2+ permeable channels in the plasma membrane in the context of paclitaxel mediated neurotoxicity. Confocal microscopy revealed that the inositol-trisphosphate receptor (InsP3R) type 1 was typically concentrated close to the plasma membrane which is in contrast to homogenous ER distribution. G protein-coupled designer receptors as well as Ca2+ imaging with Ca2+ sensitive dyes were then used to further elucidate phosphoinositide mediated Ca2+ signaling. This approach confirmed that InsP3 mediated Ca2+ signals originate close to the plasma membrane and are amplified by Ca2+ entry through TRPV4 channels. In addition, we could show that InsP3R1 and TRPV4 physically interact and are partially colocalized. In the context of paclitaxel-induced neurotoxicity, inhibition of the lipid kinase PIP5K1C upstream of InsP3 generation, NCS-1 mediated InsP3R modulation or blocking Ca2+ influx through TRPV4 channels prevented cell death. In summary, these results provide evidence for pathophysiologicaly relevant Ca2+-signaling microdomains linking the cation channel TRPV4 in the plasma membrane and InsP3Rs in the ER. Our findings underline the usefulness of designer receptors exclusively activated by designer drugs and suggest several potential strategies for prevention of paclitaxel-induced neuropathy.

Title: Acute estrogen causes a prolonged alteration of intracellular calcium signaling in basal forebrain neurons of F344 rats

Authors: ***D. A. MURCHISON**, A. S. FINCHER, W. H. GRIFFITH;
Dept. of Neurosci. and Exptl. Therapeut., Texas A&M Hlth. Sci. Ctr., Bryan, TX

Abstract: Estrogenic signaling modulates neuronal function in numerous ways in a variety of brain regions. However, promising early results related to cognition and neuroprotection in animal models have not translated well into therapeutic approaches to health issues of post-menopausal women. Our lab has been exploring the neurophysiology of acute and chronic estrogen signaling in a rat model of reproductive aging in order to identify mechanisms that could be targeted to relieve age-related impairments. We have focused on basal forebrain (BF) cholinergic neurons because of their involvement in age-related cognitive decline. Previously, we found that age-related cognitive impairment in F344 male rats was associated with enhanced intracellular Ca^{2+} buffering and reduced inhibitory synaptic transmission in cholinergic BF neurons. In ovariectomized (OVX) reproductively senescent (RS) females, chronic estrogen treatment (OVX+E, 3 weeks subcutaneous pellet) restored Ca^{2+} buffering and inhibitory transmission to youthful levels. Furthermore, we observed that acute estrogen applications (100-200 nM 17-β estradiol) reduced inhibitory synaptic transmission, increased excitatory transmission, inhibited voltage-gated currents and activated intracellular Ca^{2+} signaling. Many of these acute effects persisted in aged females, but were lost by middle-age in males. Here, we report that disruptions of intracellular Ca^{2+} homeostasis arising from acute estrogen applications are reduced in young adult (4-6 mo) female rats, relative to young males or RS females. We used fura-2 fluorescent Ca^{2+} imaging on acutely dissociated BF neurons from young adult male and female rats, as well as, RS OVX and OVX+E females (14-17 mo) to examine the impact of acute estrogen on Ca^{2+} signaling. Up to 12 min following a 3 min exposure to acute estrogen, the amplitude of evoked Ca^{2+} transients was increased relative to controls in all test groups. The increases were: young female 25%, young male 58%, OVX 22% and OVX+E 37%. Similar

increases were seen in the baseline Ca^{2+} concentration 5-15 min following acute estrogen: young female 21%, young male 74%, OVX 104% and OVX+E 73%. Note that for these parameters, chronic estrogen did not restore the values to youthful levels. Preliminary experiments suggest that some of these effects may be mediated through L-type (Ca_V1) Ca^{2+} channels, as the antagonist nifedipine (10 μM) reduced the baseline concentration increase in young males from 57 nM to 28 nM. These findings support the idea that disruption of normal Ca^{2+} signaling in the brain by acute estrogen may be detrimental to cognitive function during aging.

Title: Regulation of NMDA receptor phosphorylation by multiple calcium signaling pathways

Authors: *R. V. OMKUMAR, M. JOHN, M. KUMAR, J. JAMES, M. MAYADEVI;
Rajiv Gandhi Ctr. For Biotech., Thiruvananthapuram, India

Abstract: Calcium influx through N-methyl-D-aspartate receptors (NMDAR) and voltage gated calcium channels (VGCC) plays major roles in postsynaptic signaling mechanisms. Eventhough these pathways converge at the level of free calcium release in the cytosol, they maintain specificity towards their respective targets that are further downstream. Calcium influx through different channels may differ in their levels and durations, in the physiological context during which they occur as well as in the subcellular regions where they occur. NMDAR subunit GluN2B is phosphorylated at Ser^{1303} (*J Biol Chem. 1996, 271, 31670-8*). Phosphoryation at this site is a prominent event in cell culture systems as well as *in vivo* (*Int. J. Neuropsychopharmacol., 2010, 13, 1255-1260*). Binding of CaMKII to GluN2B is inhibited by phosphorylation at this site (*J Biol Chem. 2000, 275, 23798-806*). The conductance of NMDAR channel also depends on the phosphorylation status of the site (*Cell 2010, 140, 222-234*). GluN2B-Ser^{1303} phosphorylation level is likely to be sensitive to calcium signaling since the

calcium sensitive kinases, CaMKII (*J Biol Chem. 1996, 271, 31670-8*) and PKC (*Mol. Pharmacol., 2001, 59, 960*) are known to phosphorylate this site. Protein phosphatase 1 dephosphorylates this site (*Neurochem. Int. 2012, 61, 961-5; PLoS One, 2012, 7, e34047*). Despite the available data, the functional significance of phosphorylation at this site is not completely understood. In this study, we explored whether calcium signaling through NMDAR and VGCC differed in their effect on phosphorylation status of GluN2B-Ser^{1303} in the rat *in vivo* model. VGCC was activated by intraperitoneal (IP) injection of the VGCC activator, BayK8644 and NMDAR was activated by intracerebroventricular (ICV) injection of NMDA in separate experimental groups. Subsequently, the levels of phospho-GluN2B-Ser^{1303} in the cortex and in the hippocampus were monitored by western blotting. We find that phosphorylation at this site increases in response to Ca^{2+}-influx through either channel. However the level of GluN2B remains largely unchanged indicating that the effect is brought about by kinases or phosphatases. The effects could be prevented by prior ICV administration of the specific blockers of these channels such as MK-801 for NMDAR and nifidipine for VGCC. The effect was also blocked by pretreatment of the animals with ICV administration of KN-93 indicating that it is mediated through CaM kinase. The levels of phosphorylation of GluR1 are also being analysed. We conclude that under *in vivo* conditions, calcium influx through either NMDAR or VGCC activates CaM kinase. This in turn phosphorylates GluN2B-Ser^{1303}.

Title: Relationship between ketamine-induced toxicity and nmda receptor-mediated calcium influx in developing neurons

Authors: *C. WANG, F. LIU, T. A. PATTERSON, M. G. PAULE, W. SLIKKER, Jr;
Divi Neurotoxicol, Natl. Ctr. for Toxicological Res., Jefferson, AR

Abstract: Ketamine, a noncompetitive NMDA receptor antagonist, is used as a general anesthetic and recent data suggest that anesthetics can cause neuronal damage when exposure occurs during development. To elucidate the underlying mechanisms associated with ketamine

neurotoxicity, neural cells were harvested from the forebrain of newborn rats and neural stem cells were isolated from gestational day 16 rats. To determine the effect of ketamine on developing neurons and undifferentiated neural stem cells, cultures were exposed to 10 μM ketamine for 24 hours. Ketamine exposure resulted in elevated NMDA receptor (NR1) expression in primary cultures, and enhanced damage of developing neurons including those differentiated from the neural stem cells. However, the viability and proliferation rate of neural stem cells were not significantly affected after ketamine exposure.
Since NMDA receptor-regulated ion channels are known to be highly permeable to calcium, a study to monitor the presence of, and/or changes in, intracellular calcium concentrations would be informative. Calcium imaging data indicated that 50 μM NMDA did not cause a significant influx of calcium in typical neural stem cells; however, it did produce an immediate elevation of intracellular free Ca^{2+} $[Ca^{2+}]_i$ in neurons differentiated from the same neural stem cells. NMDA (50 μM) also produced an elevation in $[Ca^{2+}]_i$ in both control and ketamine-exposed neurons in the primary cell cultures, and a significant increase in $[Ca^{2+}]_i$ was detected in ketamine-exposed neurons compared with control neurons after NMDA stimulation.
These findings suggest that prolonged exposure of developing neurons to ketamine produces an increase in NMDA receptor expression (compensatory up-regulation) which allows for a higher/toxic influx of calcium into neurons once ketamine is removed from the system, leading to neuronal cell death likely due to elevated reactive oxygen species generation. The absence of functional NMDA receptors in cultured neural stem cells may help to explain why clinically-relevant concentrations of ketamine did not affect undifferentiated neural stem cell viability.

Title: Suppression of peripheral sympathetic activity underlies agmatine-mediated hypotension

Authors: *Y. KIM[1,2], S. CHUNG[2];
[1]Yonsei Univ. Col. of Med., Seoul, Korea, Republic of; [2]Brain Korea 21 Project for Med. Science, Yonsei Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Agmatine is highly expressed in endothelial cells and vascular smooth muscle cells. It plays a crucial role in regulating blood pressure via the modulation of peripheral vascular tone.

Although several mechanisms have been suggested to explain agmatine-induced hypotension, the precise mechanism remains to be elucidated. We investigated the effect of agmatine activation on smooth muscle contraction evoked by electrical field stimulation (EFS) in the superior mesenteric artery. In the present study, agmatine suppressed neurogenic contractions evoked by EFS in endothelium-denuded superior superior mesenteric arterial strips but did not affect contraction elicited by the external application of noradrenaline (NA). In addition, ω-conotoxin GVIA (CgTx), a selective N-type Ca^{2+} channel blocker, significantly inhibited EFS-evoked contraction, and this blockade almost completely occluded the suppression of EFS-evoked contraction by PAR-2 agonists. These findings demonstrate that activation of PAR-2 suppresses peripheral sympathetic outflow by modulating N-type Ca^{2+} channel activity, which are located in peripheral sympathetic nerve terminals, and are involved in PAR-2-induced hypotension.

Title: Characterization of the P-type voltage-gated calcium channel in chick

Authors: *Q. LI, B. ELLIOTT, E. F. STANLEY;
Krembil Res. Inst., Toronto, ON, Canada

Abstract: Transmitter release is gated primarily by P-type voltage-gated calcium channels at most mammalian synapses, while N-type channels play a lesser role. Previous research has

shown that at chick synapses (Staney and Goping, 1991) and other lower vertebrates (Thaler et al., 2001), transmission is gated almost exclusively by N-type voltage-calcium channels (CaVs). There is little published evidence to support the existence of P-type CaVs in avians, only fragmented sequences for a few species have been predicted on the NCBI database, including a small (171 amino acid) sequence for chicken (UniProtKB/Swiss-Prot: O73705.1). These findings led us to search for and characterize the P-type CaV in the chicken nervous system. We have used RT-PCR applied to whole chick brain cDNA to generate a full length P-type sequence. This sequence enabled us to design a chick-specific antibody targeted against the C-terminal of the channel. We used this to investigate the distribution of the channels in the chick brain using immunocytochemistry. We have also identified putative binding regions for ω-conotoxin GVIA and ω-agatoxin IVA. Interestingly, while the channel includes the transmembrane domains, the C-terminal is truncated and lacks a typical DxWC terminus. While we cannot as yet conclude any functional details about the channel, we do show that it is expressed in the chicken nervous system.

Title: Examination of the effects of NCLX knock-out on mitochondrial and cytosolic Ca^{2+} signaling in hippocampal neurons

Authors: Z. LIN, J. RYSTED, A. GNANASEKARAN, *Y. M. USACHEV;
Dept Pharmacol, Univ. of Iowa Dept. of Pharmacol., Iowa City, IA

Abstract: Mitochondrial Ca^{2+} transport plays an important role in regulating various physiological and pathological processes in neurons including excitability, synaptic transmission, ATP synthesis, gene regulation and neuronal response to excitotoxic stress. Recently, NCLX ($Na^+/Li^+/Ca^{2+}$ exchanger, also known as SLC8b1) has been identified as an essential molecular component of mitochondrial Na^+/Ca^{2+} exchange, the system that mediates Ca^{2+} extrusion from the mitochondrial matrix. However the role of NCLX in neurons is not well understood. Here, we used NCLX knock-out (KO) mice (Jackson Lab, C57BL6 background) to examine the role of NCLX in the control of mitochondrial and cytosolic Ca^{2+} signaling in hippocampal neurons. We

simultaneously monitored cytosolic and mitochondrial Ca^{2+} concentrations ($[Ca^{2+}]_{cyt}$ and $[Ca^{2+}]_{mt}$, respectively) using Fura-2 and mitochondria-targeted Ca^{2+} indicator mtLAR-GECO1.2 as previously described (Wu et al., Biochem J, 2014). We found that NCLX KO increased the amplitude of $[Ca^{2+}]_{mt}$ elevation (by ~2-fold) produced by strong depolarization (50 mM KCl, 30 s) and also slowed its recovery toward the baseline by ~two-fold compared to hippocampal neurons from WT mice. In contrast, NCLX KO did not have a significant effect on either amplitude or duration of $[Ca^{2+}]_{mt}$ responses evoked by mild depolarization (20 and 30 mM KCl, 30 s) or by 100 μM glutamate (30 s). NCLX KO also did not significantly affect depolarization- or glutamate-induced $[Ca^{2+}]_{cyt}$ changes. A characteristic feature of NCLX is that it can use Li^+ instead of Na^+ to transport Ca^{2+}. Notably, we found that replacement of Na^+ with Li^+ halted Ca^{2+} removal from mitochondria in WT hippocampal neurons. In contrast, Na^+ replacement with Li^+ did not slow Ca^{2+} extrusion from mitochondria in WT sensory dorsal root ganglion (DRG) neurons. These results suggest that NCLX mildly contributes to mitochondrial Ca^{2+} transport in hippocampal neurons under certain experimental conditions (e.g., strong depolarization), and that its role in mitochondrial Ca^{2+} transport may differ between central and peripheral neurons.

Abstract: The beta-pancreatic cells are in charge of producing and secreting insulin. These cells are electrically excitable and capable of generating action potentials (AP) spontaneously or in response to a stimulus. This electrical activity correlates with the secretory activity and is

orchestrated by ion channels. As a consequence, metabolic signals that modify the functional expression of these channels will alter the secretion pattern. Two hormones that regulate the voluntary food intake are Ghrelin (Ghr) and Leptin (Lep) by increasing or decreasing plasma insulin release alter glucose concentrations. In this context, the study of the electrophysiological mechanisms in beta-pancreatic cells associated to the effects of Ghr/Lep may shed light on the molecular processes involved in the endocrine/metabolic balance. In this work, we used the clonal insulin-producing RIN-M5f cell line as a model system and studied the effects of the chronic treatment of Ghr and Lep on the functional expression of voltage gated Ca^{2+} channels. Cell were kept in culture for 5 days in RPMI-1640 medium, supplemented with FBS 10%, L-glutamine (2%) and 1% penicillin-streptomycin and subjected to electrophysiological recording using the patch-clamp technique in the whole cell configuration in its two versions: current clamp and voltage clamp to dissect out the components of the Ca^{2+} current. In control conditions, the RIN-M5f cells displayed a pattern consisting of two states, silent and active. Interestingly Lep (10 nM, 72 h) significantly increased the frequency of the spontaneous APs and affected the morphology of the cells. Likewise, both Lep and Ghr treatment (10 nM, 72 h) significantly increased calcium current density from 13.2 ± 1.4 pA/pF in control cells, to 19.4 ± 2.8 and 25.2 ± 6.3 after Ghr and Lep treatment, respectively. Time course with Ghr 10 nM [0, 24, 48 and 72 h] showed increased currents as a function of exposure time. The analysis of the components of the calcium current showed that Ghr and Lep increased both LVA and HVA Ca^{2+} channels compared to the control. Hence, Ghr and Lep caused a 5- and 2.7-fold increase; respectively, in current amplitude through LVA channels. Likewise, Ghr and Lep treatment caused an increase in current amplitude of about 0.6- and 3.2-fold respectively, in current amplitude through HVA channels. Taken together these results suggest that Ghr or Lep long-term exposure increases calcium current density in RIN-M5f cells. It would be interesting how the changes in Ca^{2+} channel functional expression are related with the increase in electrical activity recorded in the cells after hormone treatment, and whether these changes in conjunction affect insulin release.

Title: Differential translocation *In vitro* and *In vivo* of two closely related Neuronal Calcium Sensor Proteins Neurocalcin delta and Hippocalcin

Authors: *J. ZHANG[1], J. VIVIANO[1], A. KRISHNAN[2], P. BELAN[3], V. VENKATARAMAN[2]; [1]Grad. Sch. of Biomed. Sci., [2]Rowan Univ. Sch. of Osteo. Med., Stratford, NJ; [3]Bogomoletz Inst. of Physiol., Kiev, Ukraine

Abstract: Neuronal Calcium Sensor (NCS) proteins play a crucial role in mediating calcium signaling, which is critical for neuronal functions. The calcium-binding motif in these proteins are the EF hands. The calcium-myristoyl switch, which promotes calcium-dependent movement of the proteins to the membranes is another characteristic feature of this group of proteins. All proteins of this family are myristoylated at the N-terminus. Two NCS proteins, Hippocalcin (HPCA) and Neurocalcin delta (NCALD), share 88% identity and 95% similarity with each other. Yet they are non-redundant as shown by data from our and other laboratories. In order to investigate the differences in their properties, especially their response to changing calcium, two different approaches were used. For *in vitro* studies, bacterially expressed and purified proteins were assayed for their ability to bind to isolated membrane fractions in a calcium-dependent fashion. For *in vivo* studies, YFP-tagged NCALD and HPCA constructs were independently transfected into COS7 cells and calcium-dependent translocation was monitored. The results demonstrate significant differences in translocation between NCALD and HPCA.

Title: Dopamine transporter amino and carboxy termini synergistically mediate ack1-dependent endocytosis

Authors: *C. G. SWEENEY, B. P. TREMBLAY, H. E. MELIKIAN;
Brudnick Neuropsychiatric Res. Inst., Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract: Dopamine (DA) signaling is central to movement, cognition, motivation, and reward. Following vesicular release, extracellular DA levels are temporally and spatially constrained by presynaptic reuptake, mediated by the dopamine transporter (DAT). DAT surface expression is acutely modulated by psychostimulants, such as cocaine and amphetamine, and by cellular signaling proteins, such as protein kinase C (PKC). Under basal conditions, DAT traffics from and to the plasma membrane via endocytosis and recycling, and an Ack1-mediated negative regulatory endocytic mechanism (endocytic brake) stabilizes DAT at the plasma membrane. PKC inactivates Ack1, releases the endocytic brake, and stimulates DAT, but not serotonin transporter (SERT), internalization. Reports from our laboratory and others independently implicate both DAT intracellular N- and C-termini as required for the endocytic brake. However, whether 1) Ack1 associates with DAT intracellular domains and 2) whether an independent braking mechanism exists at both N- and C-termini or one synergistic mechanism requiring both domains remains unknown. To test whether DAT N- and C-termini work synergistically to impose the endocytic brake, we generated DAT/SERT chimeras in which we replaced DAT N-, C-, or both termini with those of SERT. We made the reciprocal substitutions on SERT, substituting intracellular DAT domains. DAT and SERT are homologous transporters, yet they share little sequence identity at their N- and C-termini. They both undergo PKC-stimulated endocytosis, but only DAT requires Ack1 inhibition for this process. This finding poses Ack1 as a potential candidate for mediating the hypothesized synergy between DAT's N-and C-termini. We first tested that each of the DAT/SERT chimeras functions properly via [^{3}H]DA or [^{3}H]5HT uptake kinetics. Next we tested via internalization assay whether DAT N- and C-termini are required to release the endocytic brake in response to Ack1 inhibition with AIM-100. Substituting SERT's N- or C- termini alone onto DAT did not affect AIM-100 stimulated endocytic rates; however, placing both SERT domains on DAT abolished Ack1-mediated endocytic braking. These findings suggest that while, individually, each DAT terminus is not required independently for the brake, they may synergistically facilitate the braking scaffold. Tests using SERT chimeras expressing DAT N- and C-termini will address the sufficiency of these domains in this process. Future studies will also test whether Ack1 and DAT associate via N- and/or C-terminal-dependent processes.

Title: Using *Drosophila melanogaster* as a model to study how regulated dopamine transporter trafficking impacts psychostimulant associated reward

Authors: *R. R. FAGAN[1], P. EMERY[2], H. E. MELIKIAN[3];
[2]Neurobio., [3]Brudnick Neuropsychiatric Res. Inst., [1]Univ. of Massachusetts Med. Sch., Worcester, MA

Abstract: The neurotransmitter dopamine (DA) is essential for movement, cognition and reward. The plasma membrane dopamine transporter (DAT) spatially and temporally limits DA neurotransmission in order to terminate signaling and replenish presynaptic DA stores. Recent reports have identified DAT coding variants that underlie a variety of DA-related neuropsychiatric conditions, including attention-deficit/hyperactivity, autism spectrum and bipolar disorders. Thus, DA-related behaviors are highly sensitive to intact DAT function. Addictive psychostimulants, such as cocaine and amphetamine, are competitive DAT inhibitors and substrates, respectively, that perturb DA reuptake and increase extracellular DA concentrations. In addition to pharmacological inhibition, DAT activity is acutely diminished in response to protein kinase C (PKC) activation and amphetamine exposure via dynamic endocytic trafficking. Studies from our lab and others have demonstrated that numerous proteins, including the small, neuronal GTPase, Rin (RIT2) and the nonreceptor tyrosine kinase, Ack1, are critical factors in controlling DAT surface stability and endocytic response to PKC stimulation. However, it is unknown whether these regulators of DAT endocytosis play a requisite role in establishing DA-related behaviors such as reward. *Drosophila melanogaster* is a powerful tool for studying the consequences of altered DA homeostasis and DAT function *in vivo*. In particular, 3rd instar *Drosophila* larvae express ~120 DAergic neurons, and are a simple model system to study associative learning and reward behaviors *in vivo*. A recent report by Rohwedder and colleagues found that DA neurotransmission by the four primary protocerebral anterior medial (pPAM) neurons is both necessary and sufficient for odor-sugar associative reward. Here we show that wild-type *Drosophila* larvae also exhibit significant odor-amphetamine associative reward. The simple and efficient design of this behavioral paradigm will facilitate further exploration of the role of *Drosophila* Rin and Ack1 homologues in regulated DAT surface expression and rewarding behaviors.

Title: Role of G protein betagamma subunits in amphetamine-stimulated increase in extracellular dopamine

Authors: *S. S. HARRIS[1], M. TERMINEL[2], E. CASTANEDA[3], J. C. MAUNA[4], E. THIELS[4], G. E. TORRES[1];
[1]Pharmacol. and Therapeut., Univ. of Florida, Gainesville, FL; [2]Neurosci. and Exptl. Therapeut., Texas A&M Univ., College Station, TX; [3]Psychology, Univ. of Texas at El Paso, El Paso, TX; [4]Neurobio., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: The dopamine transporter (DAT) plays a role in several psychiatric disorders, including ADHD, narcolepsy and drug addiction. DAT is also a molecular target for amphetamines, used in the treatment of both ADHD and narcolepsy. However, due to their rewarding and addictive properties, amphetamine use can lead to abuse and addiction. Amphetamines increase synaptic levels of DA by binding to DAT and causing efflux DA through DAT. The mechanism by which amphetamines induces DA efflux is not understood. Therefore, it is important to identify the molecular events involved in the actions of amphetamines. Our lab has identified a novel interaction between G protein βγ subunits and DAT that plays a role in DAT function. Our *in vitro* studies, using cell systems, show that activation of Gβγ subunits with the Gβγ activator mSIRK promotes DA efflux through DAT, similar to the actions of amphetamine and inhibition of Gβγ subunits by the Gβγ inhibitor gallein decreases amphetamine-induced DA efflux. Moreover, findings from our *in vivo* studies show that inhibition of Gβγ activation by both systemic gallein administration and local infusion of gallein into the nucleus accumbens, a brain region important for both the rewarding and locomotor activating effects of amphetamine, results in an attenuation of amphetamine-induced increase in locomotor activity in rats. The proposed study sought to determine whether a potential mechanism for the effects of Gβγ inhibition on amphetamine-induced locomotor activity is the involvement of Gβγ subunits in amphetamine-induced increase in extracellular DA levels in the nucleus accumbens using *in vivo* microdialysis. Rats underwent stereotaxic surgery to implant a guide cannula into the nucleus accumbens. Following recovery from surgery, the animals were implanted with a microdialysis probe through the guide cannula and extracellular DA levels were assessed by HPLC with electrochemical detection. DA levels were monitored prior to treatment of the animals with gallein and/or amphetamine. The animals were first

administered gallein (or vehicle) and 30 minutes later amphetamine (or vehicle) and extracellular DA levels continued to be monitored following amphetamine treatment. Our preliminary results show that inhibition of Gβγ activation by gallein results in attenuation of amphetamine-induced extracellular DA levels in the nucleus accumbens. The result suggests that the Gβγ-DAT interaction plays a role in both amphetamine-induced increases in extracellular DA levels and locomotor activation. The results of the present study expand our current understanding of the molecular mechanisms responsible for amphetamine's actions in the brain.

Title: Presynaptic determinants of dopamine signaling *In vivo* elucidated via forward genetic analysis of swimming induced paralysis (Swip)

Authors: *O. REFAI[1], J. HARDAWAY[3], C. L. SNARRENBERG[3], S. ROBINSON[4], S. L. HARDIE[3], P. FREEMAN[4], R. D. BLAKELY[2];
[1]Biomed. Sci., [2]Dept. of Biomed. Sciences, Charles E. Schmidt Col. of Med. and Brain Inst., Florida Atlantic Univ., Jupiter, FL; [3]Grad. Neurosci. Program, Vanderbilt Univ., Nashville, TN; [4]Life and Physical Sci., Fisk Univ., Nashville, TN

Abstract: Dopamine (DA) is a phylogenetically conserved neurotransmitter that regulates a variety of complex behaviors. The presynaptic, DA transporter (DAT) acts to limit DA action at synaptic and extra-synaptic DA receptors. In humans, mutations impacting DAT protein expression or structure are associated with multiple brain disorders including schizophrenia, juvenile Parkinsonism/dystonia, and addiction. Loss of function mutations in the nematode *C. elegans dat-1* gene result in a phenotype termed Swimming-induced paralysis (Swip). The Swip phenotype of *dat-1* mutants can be rescued by either treatment of animals with the vesicular monoamine transporter (*cat-1*) inhibitor reserpine or by a genetic cross to animals lacking expression of the TH ortholog CAT-2, or the D2-type DA receptor DOP-3. In a forward genetic

screen for determinants of DA signaling, our lab isolated multiple, novel mutations that affect DA signaling, including alleles of *dat-1*. Here we describe our efforts to characterize two mutant lines, *vt39* and *vt44*, using genetic and pharmacological approaches. Direct genomic sequencing, and complementation tests, indicate that both lines harbor a normal *dat-1* gene. Using a single nucleotide polymorphism-based mapping approach, we find that *vt39* and *vt44* map to chromosomes I and III, respectively. Reserpine treatment rescued the Swip phenotype of *vt39* and *vt44,* similar to *dat-1* mutants, suggesting that they function in the same pathway as *dat-1*. To examine this hypothesis, *vt39* and *vt44* lines were crossed to *cat-2* or *dop-3* mutants. Here again, loss of function mutations in *cat-2* or *dop-3* rescued the Swip phenotype of *vt39* and *vt44.* Similar to *dat-1* mutants*, vt39 and vt44* exhibited osmo-sensitivity, as shown by suppression of their Swip phenotype in M9 buffer or 150mOsm sucrose medium. Since *dat-1* single mutant exhibit a highly penetrant Swip phenotype, swimming assays for *dat-1;vt39* or *dat1;vt34* double mutants may not allow for dramatic additivity. To pursue contributions of DAT-linked pathways more rigorously, we treated *vt39* and *vt44* mutants with the DAT-1 inhibitor nisoxetine, which we have shown to trigger Swip in wildtype animals within minutes of incubation. Using this reagent, we found that *vt39* and *vt44* mutants in both water and 150mOsm conditions, after treatment with 20 uM nisoxetine, revealed no significant additive effect as compared to *dat-1* animals, suggesting that the genes harbored by these mutations act in the same pathway as DAT-1. Further studies related to the identity of the genes encoding the *vt39* and *vt4*4 mutations and their functional analyses will be presented. Supported by NIH Award MH095044 (RDB) and MH093102 (JAH).

Title: Methamphetamine regulates the firing activity of dopamine neurons via a calcium-dependent potassium channel

Authors: M. LIN, D. SAMBO, *H. KHOSHBOUEI;
Box 100244, Univ. of Florida, Gainesville, FL

Abstract: Methamphetamine (METH) is a highly addictive psychostimulant. METH targets biogenic amine transporters leading to increased levels of biogenic amines in the CNS and periphery. The rewarding effects of METH are primarily due to its ability to increase dopamine levels in the brain. While METH has been shown to alter the excitability of dopamine neurons, the mechanism of METH regulation of the intrinsic firing behaviors of dopamine neurons are less understood. In this study, we identified an unexpected and unique property of METH on the regulation of firing activity of dopamine neurons. We found that although METH produced a transient augmentation (30 sec - 3 min) of the spontaneous spike activity of midbrain dopamine neurons, this was followed by a progressive reduction of the spontaneous spike activity. Careful inspection of action potentials revealed METH treated neurons exhibited increased half-width and larger coefficients of variation of the interspike interval relative to baseline, suggesting METH exposure may affect the activity of voltage-dependent potassium channels in these neurons. The unexpected finding that METH broadened the action potential and decreased the amplitude of afterhyperpolarization (AHP) led us to ask whether these two outcomes are interrelated or independent. Using excised patch single-channel recordings, first we identified BK channels in dopamine neurons by their voltage-dependence and their responses to a BK channel blocker or opener. We found while METH suppressed the amplitude of BK-mediated unitary currents, the BK channel opener NS1619 attenuated the effects of METH on action potential broadening, AHP repression, and spontaneous spike activity reduction. Live cell TIRF microscopy, electrophysiology and biochemical analysis data suggest METH exposure decreased the activity of BK channels by decreasing the level of BK-α subunits at the plasma membrane. Taken together, these data suggest BK channels may regulate the excitability of dopamine neurons and that METH regulation of the intrinsic firing behaviors of dopamine neurons is, in part, due regulation of BK channels.

Title: The sigma-1 receptor decreases methamphetamine stimulation of the dopamine transporter via a calcium-dependent mechanism

Authors: *D. O. SAMBO, M. LIN, H. KHOSHBOUEI;
Dept. of Neurosci., Univ. of Florida, Gainesville, FL

Abstract: The dopamine (DA) transporter (DAT) is a transmembrane protein implicated in multiple physiological and pathological conditions, including movement, reward, neurodegeneration, and drug addiction. DAT functions to reuptake DA from the extracellular space, making it a crucial regulator of DA homeostasis. DAT is also the primary target for methamphetamine (METH), a highly addictive psychostimulant. METH increases extracellular DA levels through interactions with DAT via at least three well-characterized mechanisms: 1) decrease in DA uptake, 2) induction of DA efflux, and 3) internalization of the transporter. Additionally, our lab and others have shown that METH increases the firing activity of DA neurons in a DAT-dependent manner. Through these mechanisms, METH has been shown to increase extracellular DA levels up to 1000% in the brain, leading to both its rewarding effects and high abuse potential. While there are currently no treatments for METH addiction, a number of studies have indicated that a protein called the sigma-1 receptor (σ_1R) is a promising target for METH addiction, with a number of studies demonstrating the efficacy of σ_1R ligands in decreasing the effects of METH. The σ_1R is a neuroprotective chaperone protein that can be activated by selective ligands. In this study, we investigated the potential mechanisms by which the σ_1R regulates METH-mediated DAT activity. We found that treatment with the selective σ_1R agonist PRE-084 prevented METH-induced, DAT-mediated increases in firing activity in dopaminergic neurons and also decreased METH-mediated DA efflux, without affecting DA uptake or DAT trafficking. Consist with these findings, we found that treatment with PRE-084 decreases METH-induced locomotor activity in rodents. To investigate the effects of σ_1R on the rewarding properties of METH, we used conditioned place preference (CPP) as a model of drug additive behavior. We found that PRE-084 treatment reduces the reinstatement of METH CPP. Currently, we are investigating the potential molecular mechanisms by which the σ_1R reduces the effects of METH. We found that the σ_1R interacts with the DAT, thus potentially influences its activity. Importantly, we showed that σ_1R activation by PRE-084 substantially reduced METH-stimulated, DAT-dependent increases in intracellular calcium levels. This is consistent with our findings that σ_1R activation decreases both METH-stimulated DA efflux and firing activity, which are both modulated by METH-stimulated calcium increases. Overall, these findings suggest that σ_1R activation may reduce the effects of METH through modulation of DAT activity and similarly decreases METH-induced behaviors.

Title: Mechanistic and behavioral characterization of the dopamine transporter using a novel allosteric modulator

Authors: *S. AGGARWAL[1], P. MENELL[2], A. CHANG[2], S. KORTAGERE[3], O. V. MORTENSEN[2];
[1]Pharmacol. & Physiol., Drexel Univ., Philadelphia, PA; [2]Dept. of Pharmacol. & Physiol., [3]Dept. of Microbiology & Immunol., Drexel Univ. Col. of Med., Philadelphia, PA

Abstract: The dopamine transporter (DAT) serves a pivotal role in controlling dopamine (DA)-mediated neurotransmission by clearing DA from synaptic and perisynaptic spaces, and controlling its action at postsynaptic DA receptors. Major drugs of abuse such as amphetamine and cocaine interact with DAT to mediate their effects by enhancing extracellular DA concentrations. Thus, DAT is a viable target for the treatment of psychostimulant abuse and addiction. We have recently identified a novel allosteric site that lies outside the central substrate and inhibitor binding pocket of DAT. This allosteric site was identified using information derived from comparative modeling of human and parasite *Schistosoma mansoni* monoamine transporters. Site-directed mutagenesis has validated the functional significance of this allosteric site. In addition, the hybrid structure–based (HSB) method has identified conformation-specific molecules that can potentially stabilize the transporter in certain beneficial conformations that may alter its interaction with cocaine and amphetamine without affecting uptake activity of DA. Interestingly, KM822, one of the ligands identified in a virtual screening experiment, was found to decrease the affinity of cocaine for DAT by 3-folds in an *in vitro* cell-based assay. In addition, KM822 also reduced the potency of cocaine towards DAT-mediated DA reuptake inhibition in an *ex vivo* model of striatal synaptosome preparations. The preliminary *in vivo* effects of KM822 on cocaine potency were tested on psychostimulant-associated behaviors in a planarian model where KM822 specifically inhibited the locomotion elicited by DAT-interacting stimulants amphetamine and cocaine. To further identify the structural determinants of KM822 allosteric binding site, we are employing substituted cysteine scanning accessibility methods (SCAM) and biotinylation experiments to identify residues that directly interact with KM822. Additional studies will be employed to determine the proximity of KM822 binding domain with the extracellular gate formed by Arg85-Asp476 salt bridge in hDAT. These studies will provide details on the role of Arg85-Asp476 extracellular gate in KM822-mediated modulation of DAT

interaction with its substrates and inhibitors. Overall, KM822 provides a unique opportunity as a molecular probe to identify novel mechanistic aspects of DAT function. In addition, it can lead to the development of more unique compounds with promising potential to treat drug addiction.

Title: Kv2.1 and the dopamine transporter interact in dopaminergic neurons

Authors: ***J. LEBOWITZ**[1], J. A. PINO REYES[2], S. STREIT[3], D. SAMBO[1], M. LIN[1], H. KHOSHBOUEI[1], G. E. TORRES[2];
[1]Neurosci., [2]Pharmacol. & Therapeut., Univ. of Florida, Gainesville, FL; [3]Col. of Medicine, Heinrich-Heine-Universität, Düsseldorf, Germany

Abstract: Parkinson's Disease (PD) is a neurodegenerative disorder that, by current estimates, is present in as many as one million Americans. A key element of PD pathology is the loss of dopaminergic neurons of the substantia nigra (SNc). The cellular mechanism for the apparent susceptibility of SNc dopamine neurons to neurodegeneration remains enigmatic. Differences in the tonic firing rate, inherent excitability, and intracellular Ca^{2+} buffering capacity in the SNc dopamine neurons are thought to contribute to the selective loss seen in PD. The dopamine transporter (DAT) regulates the dimension and duration of dopamine signaling, and is implicated in PD. Kv2.1 is a high-threshold voltage gated potassium channel that is responsible for controlling neuronal repolarization and excitability in nearly all neuronal subtypes. Since DAT carries an inward depolarizing current, and its activation increases neuronal excitability, we tested the hypothesis that a functional interaction between Kv2.1 and DAT contributes to the selective vulnerability of SNc dopamine neurons. This hypothesis in supported by our preliminary data that Kv2.1 and DAT exist in a protein complex as detected by their co-immunoprecipitation in the striatum and midbrain, two DAT-rich brain regions. In addition, we

found that all dopaminergic neurons in the SNc and ventral tegmental area (VTA) invariably express Kv2.1. The degree of Kv2.1 immunolabeling was similar in both brain regions. Membrane Kv2.1 exists in both non-conducting clusters and conductive non-clustered forms. Channel declustering is coupled with a hyperpolarization of activation voltage, presumably to protect neurons from excitotoxicity. Declustering of Kv2.1 complexes has been shown to be mediated by intracellular Ca^{2+} release via the activation of calcineurin. Previous work by our group has also shown that DAT activation by methamphetamine increases intracellular Ca^{2+}. While our data strongly support the idea that Kv2.1 is expressed at the membrane of dopamine neurons and it is potentially colocalized with DAT, whether DAT activation affects the ratio of conductive/non-conductive channels is not known. Ongoing high-resolution imaging and electrophysiological experiments will examine Kv2.1 activity in the SNc and VTA dopamine neurons at resting condition and following DAT activation. The results will reveal novel cellular pathways contributing to PD.

Abstract: Pathological alterations in dopamine (DA) homeostasis have been implicated in multiple neuropsychiatric disorders including Attention-Deficit/Hyperactivity Disorder (ADHD).

In an effort to identify penetrant genetic changes in DA signaling that drive ADHD risk and generate improved, construct-valid animal models of ADHD, the Blakely lab screened for rare coding variation in the DA transporter (DAT, *SLC6A3*) in ADHD subjects, identifying the Ala559Val substitution. *In vitro* studies revealed that the Val559 substitution promotes spontaneous DA efflux that can be antagonized by both methylphenidate (MPH) and amphetamine (AMPH), commonly prescribed ADHD medications. Previous work has shown that mice harboring the DATVal559 mutation display tonically-elevated extracellular DA levels as well as reductions in both AMPH-induced DA release and AMPH-induced locomotor stimulation. Here we report that, in contrast to findings with AMPH and MPH, the locomotor-stimulating actions of cocaine (COC) are completely absent in DAT Val559 mice, even at a high drug dose (30 mg/kg). Systemic COC-evoked DA elevations in the dorsal striatum are also lost in DAT Val559 mice. In the context of prior studies revealing normal DA D1 receptor agonist-induced locomotor activity, these studies indicate that key perturbations in DA signaling derive from cell-autonomous alterations in DA neuron physiology and activation. Given that one predominant difference between COC and AMPH/MPH is a high affinity interaction with the presynaptic 5-HT transporter (SERT), we hypothesized that the DAT Val559 allele induces compensations in 5-HT signaling that can inhibit locomotor activation by COC. Supporting this idea, combined inhibition of SERT and DAT through concurrent administration of the SERT blocker fluoxetine completely abolished MPH-induced locomotor activity, mimicking the actions of COC, in DAT Val559 mice. Additionally, injection of animals with the COC analog (RTI-113), which exhibits comparatively reduced action at SERT versus COC, induces dose-dependent locomotor activation in DAT Val559 mice, more closely resembling the activities of AMPH and MPH. These data support the hypothesis that the lack of COC-induced hyperlocomotion in DAT Val559 mice results from the combined high affinity targeting of DAT and SERT by COC and suggests that penetrant serotonergic plasticities have arisen in the DATVal559 model that can override DA-driven locomotor activation. Ongoing efforts seek to complement these studies through a genetic approach where the DATVal559 allele is expressed in the background of SERTMet172, a variant that demonstrates reduced sensitivity to COC.

Title: N-terminus phosphorylation in the Dopamine Transporter mediates Gβγ-stimulated dopamine efflux

Authors: *J. GARCIA-OLIVARES, J. A. BORIS, S. G. AMARA;
Natl. Inst. of Mental Hlth., Bethesda, MD

Abstract: Monoaminergic neurotransmission (dopamine, serotonin, and norepinephrine) is altered in complex psychiatric conditions such as depression, attention-deficit hyperactivity disorder (ADHD) and drug addiction. For dopamine, the dopamine transporter (DAT) clears extracellular dopamine through a sodium-coupled transport mechanism. The function of DAT is regulated by many intracellular mechanisms including phosphorylation, ubiquitination, and protein-protein interactions. We recently reported a novel mechanism for the regulation of DAT by heterotrimeric G proteins. We found that Gβγ subunits bind directly to the C-terminus of DAT and, upon G protein activation, the release of Gβγ results in a decrease in DA uptake. In a new set of studies, it was found that the decrease in DA uptake is a result of the promotion of DA efflux, an effect that may be similar to the DA efflux produced by amphetamines. DA efflux is dependent on calcium, sodium, and membrane potential. It also involves phosphorylation of the N-terminus by Serine/Threonine kinases such as protein kinase C (PKC) and calmodulin kinase II (CamKII). Using radiolabeled DA to measure DAT function, we are now exploring whether the DA efflux promoted by the activation of Gβγ subunits also requires phosphorylation of the N-terminus. We used two DAT mutants, hDAT-S/A and hDAT-S/D. One mutant has the five N-terminal serines (S2, S4, S7, S12, S13) substituted with alanine (S/A) to eliminate phosphorylation and the other mutant contains aspartate residues at these sites (S/D) to mimic a phosphorylated state. The induction of [3H]-DA efflux by mSIRK, a peptide that binds and activates Gβγ, was abolished in the mutant carrier hDAT-S/A, suggesting that the serine residues are important for the Gβγ-stimulated efflux. We also used pharmacological tools to inhibit kinases and phosphatases to explore how the general phosphorylation state of DAT is important in the regulation of DAT by Gβγ subunits. Our data suggest that the effect on uptake and efflux mediated by Gβγ activation is dependent on the availability of phosphorylation sites in the DAT N-terminus. Our current efforts aim to establish whether the substitutions of putative phosphorylation sites modify the binding of Gβγ to the C-terminus and whether phosphorylation is required for the conformational transitions that shift the transporter into an efflux mode.

Title: Dopamine transporter interactome when exposed to psychostimulants

Authors: S. INGRAM, T. RANA, *J. S. GOODWIN;
Biochem. and Cancer Biol., Meharry Med. Col., Nashville, TN

Abstract: The dopamine transporter (DAT) is a neurotransmitter transporter essential for the reuptake of released dopamine (DA) in the brain. DAT is one of the main targets for psychostimulants leading to a disruption of DA homeostasis. To begin to understand what proteins regulate this process, we used tandem mass spectrometry to examine the interacting proteome of DAT when exposed to methamphetamine, a DAT substrate, and cocaine, a DAT blocker. Here we provide a comprehensive qualitative analysis of proteins detected in response to psychostimulant treatment. Already known interacting proteins such as PKA, PKC, and alpha-synuclein were detected with variability based on treatment. Post spectroscopy analysis revealed novel protein interactions including redox, actin-binding, calcium binding/regulating, and voltage-dependent proteins based on drug treatment. Our MS data provides evidence that differential binding proteins are involved in DAT-mediated drug response.

Title: Aberrant dopamine D2 autoreceptor regulation of the dopamine transporter in striatal dopaminergic terminals of mice expressing the ADHD-associated dopamine transporter variant DAT Val559

Authors: *R. GOWRISHANKAR[1,2,3], G. L. DAVIS[1,2,3], A. M. STEWART[1,2], J. S. RIELE[4], M. K. HAHN[1,2], R. D. BLAKELY[1,2];
[1]Dept. of Biomed. Sciences, Charles. E. Schmidt Col. of Med., Florida Atlantic Univ., Jupiter, TN; [2]Brain Inst., Florida Atlantic Univ., Jupiter, FL; [3]Neurosci. Grad. Program, [4]Neurosci. Undergraduate Program, Vanderbilt Univ., Nashville, TN

Abstract: Dopamine (DA) D2 autoreceptors (D2ARs) play a central role in modulating DA signaling at DA terminals by reducing DA synthesis, by inhibiting DA vesicular release and by enhancing the surface availability of the presynaptic DA transporter (DAT), although the details of the latter interaction in vivo are poorly defined. DAT is responsible for terminating DA signaling at the synapse and is the target for the most common pharmacological therapies for Attention-Deficit/Hyperactivity Disorder (ADHD), amphetamine (AMPH) and methylphenidate (MPH). We previously reported that mice expressing the ADHD-associated DAT variant Val559 exhibit pronounced elevations in extracellular DA and decreased depolarization-induced vesicular DA release from DA terminals in the striatum. Moreover, we demonstrated that reduced vesicular DA release was sustained by high tonic DA stimulation of presynaptic D2ARs. Here we report that DAT Val559 mice exhibit a loss of D2AR-dependent tyrosine hydroxylase (TH) phosphorylation at Ser40, a function shown previously to be important for D2AR regulation of DA signaling. In order to understand how elevated DAergic tone affects D2AR regulation of DAT, we pursued slice biotinylation studies, where we could demonstrate a basal elevation of striatal DAT surface protein levels that, unlike wildtype DAT, cannot to be further enhanced by D2AR stimulation with quinpirole. Finally, we probed striatal slices for evidence of altered DAT phosphorylation at Val559, a site previously demonstrated to support DAT-mediated DA efflux in response to AMPH. Here, we demonstrated elevated basal Thr53 phosphorylation in DATVal559 slices along with an inability of D2AR stimulation to enhance phosphorylation, whereas slices from wildtype animals support D2AR elevations in Thr53 phosphorylation. Collectively, our data raise the possibility that aberrant presynaptic D2AR

signaling, observed either in DA synthesis capacity, DA release or DA clearance, may contribute to the pathophysiology of ADHD.

Title: Dopamine transporter expression evaluated in perinatally asphyxiated rats

Authors: *S. J. LOPEZ-PEREZ[1], J. U. MORA-VENADERO[2];
[1]Univ. of Guadalajara (CUCBA), Zapopan, Jalisco, Mexico; [2]Cell. and Mol. Biol., Univ. of Guadalajara, Guadalaara, Mexico

Abstract: The perinatal asphyxia (PA) produces alterations in the mammal Nervous System, and it is related with the development of the specific neurochemistry conditions in the dopaminergic system, that could be associate with ADHD, schizophrenia and depression. The dopamine transporter (DAT) it is responsible to maintaining the normal extracellular levels of dopamine in prefrontal cortex and striatum, and decrements in its expression could be important in the generation of neurochemistry substrates of these pathologies. Previous evidence suggest that AP event should modify DAT expression, therefore, the objective of this work was to analyze the DAT expression in juvenile rats, which were asphyxiated perinatally. At 11 days old, female and male rats were asphyxiated for 45 min in a small sealed asphyxia chamber; when the animals reached 30 days old, were sacrificed to obtain the prefrontal cortex and striatum, regions which were homogenized in RIPPA buffer supplemented whit protease inhibitors. Homogenized were centrifuged to collect the supernatant and total content of proteins was estimated in it. 80 µg of proteins were used to make a Western blot and analyze quantitatively the levels of DAT expression, using the 3-3´-diaminobenzidine tetrahydrochloride. Results showed higher DAT expression level in frontal cortex and striatum of asphyxiathed animals, independently of sex. Previously, we demonstrated a low dopamine release in frontal cortex from 30 days old male rats, so the overexpression of DAT reported here may reflect a compensatory mechanism to uptake the dopamine that maybe is flowing far away of synapse, in view of the dopaminergic volume transmission fact. This work was partially supported by P3E UDG founding.

Title: Identification of residues involved in the dopamine transporter-G betagamma interaction and dopamine efflux

Authors: ***J. A. PINO**[1], M. H. CHENG[3], F. PULLARA[3], A. GOPINATH[2], K. SAHA[2], J. LEBOWITZ[2], H. KHOSHBOUEI[2], J. GARCIA-OLIVARES[4], S. G. AMARA[4], I. BAHAR[3], G. E. TORRES[1];

Abstract: The dopamine transporter (DAT) plays a crucial role in the regulation of brain dopamine (DA) homeostasis. Through re-uptake of DA, DAT serves two important functions: the termination of synaptic transmission at dopaminergic terminals, and the replenishment of vesicular DA pools. In addition to uptake, DAT can also function to release DA. This process, which is referred to as DAT-mediated efflux, is the mechanism used by potent and highly addictive psychostimulants, such as amphetamine and its analogues, to increase extracellular DA levels in motivational and reward areas of the brain. It has long being recognized that DA neurons release DA through exocytotic and non-exocytotic processes. However, the exact mechanism by which physiological signals or psychostimulants, such as amphetamine, induce DA efflux through DAT still remains a complex and not completely understood area of research. Thus, examining the basic mechanism(s) that affect DA efflux through DAT is critical for both understanding fundamental aspects of DA regulation and clinical intervention in DA-related brain disorders associated with the therapeutic use and abuse of psychostimulants. Recently, we discovered that the βγ subunits of G protein (Gβγ) bind to the intracellular carboxy-terminus of DAT and regulate transporter activity. More importantly, we have observed that activation of Gβγ promotes DAT-mediated DA efflux. However, the amino acid residues involved in Gβγ interaction site(s) in DAT and their role in transporter regulation remain largely unknown. Here, we used a combination of computational modeling, mutagenesis, immunoprecipitations, and

functional assays to identify the Gβγ binding site on DAT. Based on the Drosophila melanogaster DAT crystal structure, we used advanced molecular modeling approaches to generate equilibrium conformations for human DAT (hDAT) in different states. Simulations of Gβγ binding to hDAT indicate that Gβγ has a high propensity for binding a hot spot within the intracellular carboxy-terminus of hDAT. The model predicts that R588 and R610 in hDAT are critical for interaction with Gβγ. Preliminary functional studies are consistent with the role of these residues in Gβγ interaction with DAT and promotion of DA efflux. Thus, this study provides a detailed characterization of the DAT-Gβγ interaction and a better understanding of its contribution to DAT-mediated efflux

Title: Changes in motivation, impulsivity, cognition and DAergic signaling cascades with ADHD-associated DAT Val559 transgenic mouse.

Authors: *G. L. DAVIS[1,2,3], L. A. WALKER[4], R. D. BLAKELY[1,2];
[1]Dept. of Biomed. Sciences, Charles E. Schmidt Col. of Med., [2]Brain Inst., Florida Atlantic Univ., Jupiter, FL; [3]Grad. Neurosci. Program, [4]Neurosci. Undergraduate Program, Vanderbilt Univ., Nashville, TN

Abstract: Our lab has created a construct-valid mouse model of ADHD based on the dopamine (DA) transporter (DAT) coding variant Val559 to elucidate neurobiological mechanisms supporting Attention-Deficit hyperactivity Disorder (ADHD) and other DA-linked, comorbid disorders. Previously we demonstrated that DAT Val559 mice have altered behavioral response to amphetamine (AMPH), postulating that it was through a constitutively active D2 receptor (D2R)-DAT interaction that resulted in reduced vesicular DA release. We have further explored this altered drug response by examining downstream signaling proteins that are known to play a

role in AMPH-induced locomotor behavior, such as ERK1/2, as well as changes in cellular activation, and the possibility of rescuing effects via D2R-dependent mechanisms. Our preliminary findings indicate that downstream pathways exhibit a blunted response, mirroring the behavior. Additionally, we have sought evidence for alterations in cognitive, attention and impulsivity using the 5-choice serial reaction time task (5-CSRTT), and used progressive ratio and sucrose preference tasks to examine changes in motivation and hedonic valuation. Alterations in cognitive performance, motivation, and impulsivity were observed in the DAT Val559 mice, with no apparent changes in hedonia. DAT Val559 mice showed several key differences in the 5-CSRTT task, including faster acquisition of the task, increased impulsivity under a long delay condition, yet improved performance with a variable delay condition. Interestingly, altered impulsive responses in the context of the timing parameter of the paradigm suggests that DATVal559 mice may exhibit an alteration in timing perception. Ongoing studies seek to clarify this effect and to determine whether this alteration contributes to the increased impulsivity seen in 5-CSRTT. Additionally, the DATVal559 mice displayed increased break points in the progressive ratio task. This alteration in apparent motivation could drive the DATVal559 to hyperfocus on the parameters driving task acquisition in the 5-CSRTT and to differentially utilize the temporal information presented during training sessions, being less reliant on absolute timing expectations. Ongoing studies seek to determine the cellular and circuit level plasticities that derive from lifelong expression of the DAT Val559 variant and that lead to the observed changes in impulsivity and motivation, and determine how these related to alterations observed in AMPH and methylphenidate drug responses. Abstract: The transactivator of transcription protein, HIV-1 Tat, is linked to HIV-associated neurocognitive disorder (HAND). HIV-1 Tat is produced in $CD4^+$ cells such as microglia even with effective antiretroviral therapy. Microglial-neuronal interactions are of particular interest given the apparent susceptibility of dopamine neurons in the substantia nigra pars compacta (SNc) to neurodegeneration. We tested the hypothesis that the ratio of microglia to dopamine neurons in the SNc is higher than in the ventral tegmental area (VTA) and HIV-1 Tat exposure exaggerates this difference. Using the traditional biomarker tyrosine hydroxylase (TH), we examined the ratio of dopamine neurons and microglia in the VTA and SNc, the correlation between this ratio and the sensitivity of these neurons to the untoward effects of HIV-Tat. Contrary to our hypothesis, in wildtype C57BL6 mice, we found dopamine neurons in the SNc receive less microglial support than VTA dopamine neurons and that HIV-1 Tat exposure decreased TH immunoreactivity in the SNc but not in the VTA. In addition, a 7-day HIV-1 Tat induction did not induce microglial activation in the SNc or VTA; it reduced microglial density, decreased microglia-neuronal interaction and decreased TH immunoreactivity in the SNc without an effect on the total number of neurons in the SNc. Therefore the observed loss of TH immunoreactivity might be due to the loss of TH-phenotype in these neurons rather than neuronal death. Utilizing functional assays, our ongoing experiments examine the nature of neuronal-microglial interactions in the VTA and SNc, important in understanding differential susceptibility of dopamine neurons.

Title: Pharmacological chaperones of the dopamine transporter rescue dopamine transporter deficiency syndrome mutations in heterologous cells

Authors: *P. BEEREPOOT, V. M. LAM, A. SALAHPOUR;
Pharmacol., Univ. of Toronto, Toronto, ON, Canada

Abstract: A number of pathological conditions have been linked to mutations in the dopamine transporter gene, including hereditary Dopamine Transporter Deficiency Syndrome (DTDS). DTDS is a rare condition that is caused by autosomal recessive loss- of-function mutations in the dopamine transporter (DAT) that often affect transporter trafficking and folding. We sought to identify pharmacological chaperones of the DAT as a potential treatment for DTDS. After screening a set of known DAT ligands for their ability to increase DAT surface expression, we found that bupropion and ibogaine increased DAT surface expression, while others, including cocaine and methylphenidate, had no effect. Ibogaine and bupropion increased wild type DAT protein levels and also promoted maturation of a well-characterized ER-retained mutant K590A, suggesting an ER- level chaperoning effect. This was corroborated by pharmacologically blocking ER-exit, which eliminated the effect of ibogaine and bupropion. The rescue of K590A DAT maturation by ibogaine and bupropion is dependent on the ER-exit protein SEC24D, as knocking down or overexpressing SEC24D diminishes or enhances rescue respectively. Together the data suggest that ibogaine and bupropion stabilize a DAT conformation that promotes maturation through enhancing interaction with ER-exit machinery.Importantly, both drugs rescue DAT maturation and functional activity of the DTDS mutations A314V and R445C. Our results show that pharmacological chaperone approaches could be a viable clinical direction for increasing DAT function, particularly in DTDS and other clinical conditions associated with DAT mutations that reduce maturation. To demonstrate that these results are translational, we are currently working on a CRISPR knock-in mouse model of DTDS.

Neurobio., Natl. Inst. of Mental Hlth., Bethesda, MD; [6]Cell. and Mol. Neurobio., Natl. Institude of Mental Hlth., Bethesda, MD

Abstract: Dopamine (DA) plays a key role in a variety of behaviors, and aberrant levels of DA are thought to contribute to neuropsychiatric disorders, including Parkinson's disease, ADHD, and addiction. DA levels are regulated via reuptake into the presynaptic terminal by the DA transporter (DAT). Addictive psychostimulants target DAT and increase the levels of synaptic DA. Specifically, amphetamine (AMPH) reverses the direction of DA flux through DAT and causes DA efflux into the synapse. We discovered that G protein βγ subunits (Gβγ) interact with the intracellular carboxy-terminus of DAT, and that *in vitro* activation of Gβγ promotes reverse transport of DA through DAT similar to AMPH. Further, we demonstrated that pharmacological inactivation of Gβγ attenuates and pharmacological activation of Gβγ potentiates AMPH-induced hyperlocomotion. Here, we sought to extend these findings by examining: (1) AMPH-induced locomotor activity after intra-accumbal infusion of a peptide that targets a Gβγ-binding site on DAT (TAT-DATC), (2) the effect of pharmacological inactivation of Gβγ on AMPH-induced place preference, and (3) the effect of pharmacological inactivation of Gβγ on the AMPH-induced increase in DAT-Gβγ interaction. To address (1), adult male rats received intra-accumbal infusions of TAT-DATC (800ng/side) 30min before AMPH (3mg/kg, ip), and locomotor activity was measured in an open field test. To address (2), rats were trained on a standard conditioned place preference paradigm. Thirty min before AMPH (1.5mg/kg, ip) trials, rats were injected (4mg/kg, ip) or infused intra-accumbally (100ng/side) with gallein. Controls received vehicle injections/infusions prior to AMPH treatment. To address (3), rats received either gallein (4mg/kg, ip) or vehicle 30min before AMPH injections (3mg/kg, ip), and striatal tissue was harvested 30min later. DAT was immunoprecipitated and samples were probed for Gβγ. We found that: (1) blocking the interaction between Gβγ and DAT attenuated the AMPH-induced hyperlocomotion; (2) gallein pretreatment abolished the increase in preference for the AMPH-paired chamber; and (3) gallein pretreatment appears to blunt the AMPH-induced increase in Gβγ immunoreactivity. Collectively, these results suggest that the interaction between DAT and Gβγ is affected by AMPH, and that this interaction plays a critical role in AMPH-induced hyperlocomotion as well as AMPH-supported preference learning. Thus, the interaction between DAT and Gβγ presents a potential target for modulating AMPH action *in vivo*.

Title: Psychoactive "benzofury" compounds, 5-APB and 6-APB, mimic the effects of 3,4-methylenedioxyamphetamine (MDA) on monoamine transmission in rats

Authors: *M. H. BAUMANN[1], H. M. WALTERS[1], J. S. PARTILLA[1], B. E. BLOUGH[2], S. D. BRANDT[3];
[1]Medicinal Chem. Section, IRP, NIDA, NIH, DHHS, Baltimore, MD; [2]RTI, Research Triangle Park, NC; [3]Liverpool John Moores Univ., Liverpool, United Kingdom

Abstract: The widespread non-medical use of new psychoactive substances (NPS) is a growing public health concern. In this regard, the so-called "benzofury" compounds, 5-(2-aminopropyl)benzofuran (5-APB) and 6-(2-aminopropyl)benzofuran (6-APB), are two drugs with reported stimulant-like properties in human users. Here, we compared the pharmacology of the benzofuran compounds with the structurally-related club drug, 3,4-methylenedioxyamphetamine (MDA), using *in vitro* monoamine transporter assays in rat brain synaptosomes and *in vivo* microdialysis in the nucleus accumbens of conscious male rats. We found that 5-APB and 6-APB are substrate-type releasers at dopamine transporters (DAT) and serotonin transporters (SERT), similar to the profile of effects produced by MDA. However, the benzofuran compounds are at least 3-fold more potent than MDA at evoking transporter-mediated release via DAT and SERT. When tested *in vivo*, 5-APB (0.3 and 1.0 mg/kg, i.v.), 6-APB (0.3 and 1.0 mg/kg, i.v.) and MDA (1.0 and 3.0 mg/kg, i.v.) caused dose-related elevations in extracellular dopamine and serotonin in the brain that reached 5-fold and 10-fold above baseline, respectively. The benzofuran compounds also induced profound behavioral activation characterized by forward locomotion and stereotypic movements, effects which lasted for at least 2 h post-injection. Collectively, our findings indicate that 5-APB and 6-APB are substrate-type releasers at DAT and SERT, which produce neurochemical effects similar to those produced by the club drug MDA. Importantly, the benzofuran compounds are more potent than MDA *in vitro* and *in vivo*, and produce sustained stimulant-like effects in rats. Our data suggest that benzofuran-type compounds may have significant abuse liability, and could pose risks for adverse effects, especially if used in conjunction with abused drugs or medications which enhance overall monoamine transmission in the brain.

Title: Structural and synaptic organization of the adult reeler mouse somatosensory neocortex

Authors: *M. PRUME[1], A. ROLLENHAGEN[2], J. LÜBKE[2,3,4];
[1]Res. Ctr. Jülich Gmbh, Juelich, Germany; [2]Inst. for Neurosci. and Med. INM-2, Res. Ctr. Jülich Gmbh, 52425 Juelich, Germany; [3]Dept. of Psychiatry, Psychotherapy and Psychosomatics, RWTH Univ. Hosp. Aachen, 52074 Aachen, Germany; [4]JARA Translational Brain Med., 52074 Aachen, Germany

Abstract: The *reeler* mouse with its severe structural alterations has been a useful tool to study various aspects of cortico- and synaptogenesis. This mouse has also been widely used as a model for neurological and neurodegenerative disorders such as Alzheimer's disease and lisencephaly in humans. Though, rather little is known about possible neural structural changes in the adult *reeler* mouse neocortex. For this purpose we investigated the *reeler* somatosensory cortex with a focus on the so-called 'barrel field' using serial ultrathin sectioning, high-end electron microscopy and subsequent computer-assisted 3D-volume reconstructions of synapses and their target structures. We focused on structural correlates for synaptic transmission and plasticity, in particular the shape and size of active zones and the organization and size of the pools of synaptic vesicles.
Previous studies using layer-specific cDNA probes have demonstrated that the neocortex in *reeler* lacks the typical six-layered architecture. As revealed by cytochrome C oxidase reaction, an altered 'barrel field' still exists but is organized in patches and slabs throughout the 'cortical wall'. The cortical wall is defined as the area between layer 1 (L1) and the white matter. At the light- and electron microscopic level L1 in *reeler* is dramatically reduced in volume when compared to wild type. In general, L1 is composed of clusters of 2-4 neurons often connected via gap-junctions, 'active' oligodendrocytes and astrocytes. Strikingly, the thalamocortical projection reaches the pial surface where massive fiber bundles turn and descend and then terminate throughout the entire 'cortical wall'. These fiber bundles are always accompanied by several oligodendrocytes and clusters of neurons.
The synaptic organization in *reeler* follows the same principles of a target-specific formation of synapses as described in the normal neocortex. Synaptic boutons are established on somata, dendritic shafts, spines and axon initial segments on neurons of different identities and locations within the cortical wall.
Neurons within the cortical wall form either homologous or heterologous clusters that are also connected via gap-junctions. Thus, it may be speculated that neurons of the same phenotype

determined by their genetic fate and molecular identity form these clusters as an organization principle causally related to the lack of their prospective layers. In conclusion, neurons and their synapses seems to be of greater impact for a correct wiring and the establishment of individual networks than the formation of layers.

Abstract: Synapses are the key elements for signal transduction and plasticity in the brain, thus controlling the induction, maintenance and termination of signal transduction in any given neuronal microcircuit.
Despite a relatively large number of publications on structural and functional aspects of various synapses in the central nervous system of different animal species, very little is known about these structures in humans, in particular about their quantitative geometry. Hence, synapses in cortical layer 5 - the main output station of the neocortex and a recipient layer of thalamocortical afferents of the human temporal lobe - were investigated using serial ultrathin sectioning and digital electron microscopic images. This was followed by three dimensional (3D) volume reconstructions leading in the generation of quantitative 3D-models of synapses. We focused on structural parameters that are the most critical factors underlying synaptic transmission and plasticity, such as the shape, size, number, and distribution of active zones (AZs, functional transmitter release sites) as well as the organization and size of the three pools of synaptic vesicles, namely the readily releasable, the recycling and reserve pool. In addition, immunohistochemistry against glutamine synthetase was carried out to investigate the structural

relationship of synapses and astrocytes and thus their contribution to synaptic transmission and plasticity.
A total of 152 synaptic boutons and their target structures were completely analyzed. The majority were established either on dendritic spines (~76%) the remainder on shafts. Synaptic boutons were highly variable in both shape and size (6.20±0.77 μm^2; 0.42±0.07 μm^3**,** ranging from 0.46 to 27.33 μm^2; 0.10 to 1.93 μm^3) with a skew to middle-sized boutons. Several mitochondria (0-26) were found in the presynaptic bouton constituting ~6% of the total volume. The majority of boutons (~88%) had a single pre- (0.452±0.358 μm^2; 0.003±0,001 μm^3) and postsynaptic densities (0.405±0.100 μm^2; 0.01±0.01 μm^3), sometimes perforated. The mean total pool size of synaptic vesicles was 1580.19±255.19 (ranging from 142 to 8413) with a mean diameter of 31.99±0.87 nm. Strikingly, no correlation was found between the size of the boutons with that of mitochondria, AZs and the pool of vesicles. Synaptic complexes were surrounded by a dense network of fine astrocytic processes reaching the synaptic cleft, thus regulating the temporal and spatial glutamate concentration.
The quantitative 3D-models of synapses will lead to an improved understanding of the function of synapses in cortical networks in humans.

Title: Immunogold labeling of presynaptic proteins in developing hippocampal neurons

Authors: *J.-H. TAO-CHENG;
NINDS, NIH, Bethesda, MD

Abstract: The transport of presynaptic proteins from soma through the axon to their final destination of synaptic terminals is complex. The present study uses preembedding immunogold electron microscopy to illustrate the trafficking of various presynaptic proteins in developing rat hippocampal neurons 3-6 days in culture. Label for synaptic vesicle (SV) integral membrane proteins, including synaptophysin, SV2, synaptotagamin and VAMP, was concentrated in the Golgi complex, and typically was associated with membranous structures in neuronal somas.

These SV proteins were then transported though axon in aggregates of pleomorphic tubular-vesicular structures, often associated with microtubules. The transport aggregates (as large as 1 μm) as well as individual vesicles/vacuoles (30-300 nm) within these aggregates were heterogeneous in size and shape. These transport aggregates are structurally different from SV clusters of uniform-sized (~40 nm) vesicles. SV clusters are formed through specialized endosomal sorting after undergoing exo- and endocytosis. SV clusters are typically located in presynaptic terminals but can also exist in axons unopposed by dendrites in young cultures. Thus, SVs with a full complement of their specific proteins are not formed in the soma but in the axon. In contrast to SV proteins, label for SV-associated proteins including synapsin I and synuclein was not concentrated at the Golgi complex, suggesting that their biosynthesis may not involve passing through it. Instead, label for synapsin I and synuclein was mostly cytosolic in neuronal somas. In axons, these labels could be cytosolic or membrane associated, including structures resembling transport aggregates for SV proteins as well as SV clusters. However, labeling intensity was preferentially higher at SV clusters, and it is known that association of synapsin I with SVs is regulated by phosphorylation. These observations suggest that the two groups of proteins, SV integral membrane proteins and SV-associated proteins, proceed through different routes of biosynthesis and axon transport, and are only colocalized in SV clusters at a later stage of SV formation.

Title: Super resolution microscopy analysis of neuromuscular junction active zones in adult and aged mice

Authors: *Y. BADAWI[1], S. MORI[2], K. SHIGEMOTO[2], H. NISHIMUNE[1];
[1]Anat. and Cell Biol., Univ. of Kansas Med. Ctr., Kansas City, KS; [2]Geriatric Med., Tokyo Metropolitan Inst. of Gerontology, Tokyo, Japan

Abstract: Presynaptic active zones play a pivotal role as synaptic vesicle release sites for synaptic transmission, but the molecular architecture of active zones in mammalian neuromuscular junctions (NMJs) at sub-diffraction limited resolution and the effect of aging on mammalian NMJs remains unknown. Bassoon and Piccolo are active zone specific cytosolic proteins essential for active zone assembly in NMJs, ribbon synapses, and brain synapses. Adult mammalian NMJs depend on P/Q-type voltage-gated calcium channels (VGCCs) to trigger the synaptic vesicle release. The objectives of this study are: (1) to analyze NMJ active zones using stimulated emission depletion (STED) nanoscopy and (2) elucidate how active zone proteins are altered in NMJs of aged mice. NMJ active zones in adult (8-months old) and aged (29-months old) wild-type mice were analyzed by immunohistochemical detection of active zone-specific proteins Bassoon and Piccolo, and P/Q-type VGCCs. Dual-color STED microscopy was used to image these proteins at a resolution below the diffraction limit of light microscopy.
Bassoon, Piccolo, and P/Q-type VGCCs showed punctate distribution patterns in NMJs of adult mice. Bassoon and Piccolo are thought to colocalize and share some functions at active zones, however we demonstrate an unexpected finding of non-overlapping localization of these two proteins. P/Q-type VGCC puncta colocalized with Bassoon puncta at most active zones. Interestingly, the quantity of these proteins decreased in the NMJs of aged mice. This study revealed the molecular architecture of active zones in mouse NMJs at nanoscale resolution, and shows the selective degeneration mechanism of active zone proteins in NMJs from aged mice.

Title: Structural heterogeneity of presynaptic active zones underlies variability in synaptic latency across synapses at the frog neuromuscular junction

Authors: *A. E. HOMAN[1], R. LAGHAEI[3], M. DITTRICH[4], S. D. MERINEY[2];
[1]Neurosci., [2]Univ. of Pittsburgh, Pittsburgh, PA; [3]Carnegie Mellon Univ., Pittsburgh, PA;
[4]Carnegie Mellon Unversity, Pittsburgh, PA

Abstract: The structure of presynaptic active zones (AZs), in particular the distance of voltage gated calcium channels (VGCCs) to release sensors on synaptic vesicles, can play a large role in the function of the synapse as a whole. Due to the high order relationship between external calcium concentration and the magnitude of neurotransmitter release at the neuromuscular junction (NMJ), slight variations in the organization and/or density of VGCCs at presynaptic AZs may lead to significant variability in transmitter release across synapses. We found that synaptic latency, the time between the arrival of a presynaptic action potential to the generation of a postsynaptic response, differs considerably from synapse to synapse at the frog NMJ and hypothesized that this heterogeneity is underpinned by differences in the organization/density of VGCCs at presynaptic AZs within those synapses. Using a combination of computational modeling and physiology, we manipulated the organization and/or density of VGCCs at presynaptic AZs and analyzed the effect on synaptic latency. We found that greater distances between VGCCs and release sensors in our model led to a slowing of synaptic latency while a greater density of channels resulted in faster synaptic latencies. When we blocked channels in either the model or in experiments, synaptic latency slowed. In an effort to understand these results at the AZ level, we analyzed the spatio-temporal calcium dynamics within an AZ in our MCell model during each of the manipulations. We found that when channels were moved farther from vesicle sensors, released vesicles relied more heavily on distant channels in the AZ, likely contributing to the slowing we observe in synaptic latency. When more VGCCs were added, however, nearby channels contributed most of the calcium ions and the faster synaptic latencies were likely due to an increase in calcium sources close to the released vesicle. When VGCCs were removed from our AZ model, we found that released vesicles relied primarily on the most closely associated channel and that the slowing in synaptic latency was likely due to fewer calcium sources close to the vesicle. Our combined experimental and computational data provide evidence that small changes to the organization and/or density of VGCCs can have a large influence on synaptic latency by manipulating the spatiotemporal dynamics of calcium within AZs across synapses at the frog NMJ. These data provide evidence that the structure of AZs alone can strongly influence the dynamics of neurotransmission at a synapse.

Title: Electron microscopy analysis of synaptic vesicle tethering by calcium channels at presynaptic active zones

Authors: *R. H.-C. CHEN, E. F. STANLEY;
Krembil Res. Inst., Toronto, ON, Canada

Abstract: Neurotransmitter is released from presynaptic terminals by calcium-gated fusion and discharge of synaptic vesicles (SVs) at active zones (AZ). Based on single-channel gated fusion we predicted that SVs are tethered to calcium channels (Stanley 1993). Using a direct, in-vitro binding assay we recently reported that SVs can bind to a 49 amino acid region towards the tip of the CaV2.2 C-terminal (Wong et al. 2013, 2014). In order to investigate tethers in situ, we developed an innovative electron microscopy (EM) technique whereby non-tethered structures were flushed out of isolated presynaptic terminals by osmotic rupture prior to imaging so that the remaining tethers and tethered SVs could be easily identified within these "synaptosomal ghosts" (Wong et al. 2014). We observed two classes of tethers that were related to the distance of the SV from the AZ: multiple-short (<45 nm) or single-long (45-175 nm) tethers. We proposed a model where the SVs are 'grabbed' from the peri-AZ cytoplasm by a long G-tether and are then 'locked' by shorter L-tethers in preparation for exocytosis. Based on its amino acid backbone, we estimate that the CaV2.2 C-terminal tail could extend to a maximum of ~210nm, making it a G-tether candidate. To test this hypothesis, we generated antibodies against the C-terminal tail and used them to immunogold label ghosts. When viewed under EM, these antibodies preferentially labeled SVs and/or their tethers. The observed pattern of labeling supports the hypothesis that the CaV C-terminal tail extend from the AZ to tether SVs.

Title: Oriented docking of dense core vesicles at active zones on the presynaptic membrane of neuromuscular junctions

Authors: *J. JUNG[1], J. SZULE[2], K. STOUDER[2], U. MCMAHAN[2];
[1]Biol., [2]Texas A&M Univ., College Station, TX

Abstract: Electron tomography on tissue sections from fixed and stained frog neuromuscular junctions has provided evidence that active zone material, an organelle attached to the presynaptic membrane at synapses, plays a central role in the docking of synaptic vesicles on the presynaptic membrane prior to their fusing with it and releasing their neurotransmitters into the synaptic cleft. In particular, it has shown that active zone material macromolecules connect to specific sites on the membrane of undocked synaptic vesicles, stably orienting a predetermined fusion domain of the vesicle membrane toward the presynaptic membrane while bringing the two membranes together [Szule et al. (2012) PLoS ONE 7(3): e33333; Harlow et al. (2013) PLoS ONE 8(7):e69410]. As at other synapses, axon terminals at frog neuromuscular junctions contain, in addition to synaptic vesicles, vesicles that are larger, much less frequent and have a distinctive electron dense core. Dense core vesicles at neuromuscular junctions are likely to contain peptides that are released into the synaptic cleft to regulate formation and maintenance of synaptic apparatus in the muscle fibers. We show by electron tomography on adult frog neuromuscular junctions fixed at rest and during repetitive evoked synaptic activity that dense core vesicles dock on and fuse with the presynaptic membrane alongside synaptic vesicles and that active zone material connects to undocked and docked dense core vesicles in the same way it connects to synaptic vesicles. We conclude that undocked dense core vesicles, as do undocked synaptic vesicles, have a predetermined fusion domain, and that active zone material regulates the oriented docking of these structurally and functionally different vesicle types by the same macromolecular interactions. These findings are of interest not only because they concern the generality of active zone material function, but also because they may be useful for solving the related problems of whether the orientation of a predetermined fusion domain in a vesicle's membrane for contact with the presynaptic membrane provides advantages for normal vesicle membrane-presynaptic membrane fusion, the effective release of vesicle content into the synaptic cleft and/or the efficient retrieval of vesicle membrane from the presynaptic membrane for recycling.

Title: Characterization of a synaptic vesicle binding site on the CaV channel distal C-terminal

Authors: *S. GARDEZI, Q. LI, A. R. NATH, E. F. STANLEY;
Genes and Develop., Krembil Res. Inst., Toronto, ON, Canada

Abstract: At fast transmitting synapses neurotransmitter is released from synaptic vesicles (SVs) that are gated to fuse with the presynaptic membrane by calcium ions that enter through voltage-gated calcium channels (CaVs). There is a growing consensus that SVs associate closely to the CaVs (Stanley Neuron 1993, TINS 2016) but the molecular linking mechanisms remain poorly understood. We developed an in vitro synaptic vesicle binding assay method (SV-PD) and showed that SVs can bind to the intact CaV2.2 channel and demonstrated pull down using the distal third, C3 segment, of its long C-terminal (Wong et al 2013). The binding site was further localized to a 49 amino acid region just proximal to the C-terminal tip (Wong et al 2014). In this study we analyzed the amino acid binding motif. The SV binding site was further restricted to a 10 amino acid sequence, HQARRVPNGY, using blocking peptides and this sequence inhibited SV recycling in chick brain nerve terminals (synaptosomes). We have identified the SV binding motif within HQARRVPNGY by means of a palette of mutant blocking peptides. While we have not as yet identified the binding target on the SV itself nor do we know the specific role of the attachment site in synaptic transmission, we hypothesize that the distal C-terminal participates in the capture of the SVs from the cytoplasm for delivery to the active zone. Further, we hypothesize that additional and later interactions secure the vesicle within range of the CaV single Ca2+ domains to prime the SV for gated fusion.

Title: RIM-binding proteins are crucial for clustering calcium channels and synaptic transmission in ribbon synapse

Authors: *F. LUO[1], C. ACUNA[2], T. SÜDHOF[3];
[1]Mol. and Cell. Physiol., Hhmi/Stanford Univ., Stanford, CA; [2]Mol. and Cell. Physiol., Stanford Univ., stanford, CA; [3]Mol. and Cell. Physiol., HHMI/Stanford Univ., stanford, CA

Abstract: Ribbon synapse transmits wide-spectrum sensory information in the visual and auditory system. Here, we assess the role of a key active zone molecule, RIM binding protein (RBP), in calcium channel clustering and neurotransmitter release using a combination of genetic, electrophysiological and ultrastructural analysis of ribbon synapse between rod bipolar cell and AII amacrine cell in the mouse retina. We find that deletion of RBP1 and RBP2 does not impact synapse fine structure, but significantly impairs presynaptic calcium influx and desynchronizes transmitter release evoked by step depolarization. We propose that RBPs play essential role in speeding and synchronizing neurotransmitter release at ribbon synapse by facilitating the clustering of calcium channels within active zones.

Title: Analysis of vamp7 function at the *Drosophila* neuromuscular junction

Authors: *I. D. SANTIAGO[1], B. MELENDEZ[2], T. J. LITTLETON[3], R. JORQUERA[2,4];
[1]Neurosci., Univ. Central Del Caribe, Bayamon, PR; [2]Neurosci., Univ. Central del Caribe, Bayamon, PR; [3]Picower Inst. for Learning and Memory, MIT, Cambridge, MA; [4]Inst. de Ciencias Biomedicas, Univ. de Chile, Santiago, Chile

Abstract: Vesicle-Associated Membrane Proteins (VAMPs) are SNAREs required for intracellular membrane trafficking, targeting and fusion. Tetanus insensitive (Ti)-VAMP or VAMP7 has been found in all cell types and is thought to be involved in late endosome and lysosome fusion. In neurons, VAMP7 regulates neurite outgrowth and has been implicated in

synaptic vesicle (SV) trafficking and spontaneous SV fusion. In addition, VAMP7 gene polymorphisms have been linked in patients with bipolar disorder. However, neuronal VAMP7 function and its role in neurological disorder is not clear. Combining available genetics tools, fluorescent imaging and electrophysiology we investigate VAMP7 localization and function at the *Drosophila* neuromuscular junction (NMJ). Null animals ($VAMP7^{-/-}$) generated by imprecise p-element excision are adult lethal, but survive until third instar larva displaying sluggish phenotype. More presynaptic boutons are observed in $VAMP7^{-/-}$. Strikingly, $VAMP7^{-/-}$ did not increase the average spontaneous EPSCs frequency as we expected. Nerve stimulation in $VAMP7^{-/-}$ evoked larger quantal content and synaptic depression than control. Consistently, presynaptic loadings with FM 1-43 dye revealed increased exo/endo-cycling pool and altered reserve pool formation in $VAMP7^{-/-}$. Directed expression of VAMP7-GFP in motor neurons or postsynaptic muscles localizes the fusion protein at the plasma membrane and in intracellular compartments around the nuclei. Localization analysis at the NMJ reveal presynaptic puncta and enrichment at the sub-synaptic area. Our findings indicate altered presynaptic function in $VAMP7^{-/-}$ and a putative role in retrograde signaling at *Drosophila* NMJ.

Title: Dynamics of the Extended Synaptotagmins in the endoplasmic reticulum of neurons

Authors: *C. WHITEUS[1], J. WANG[2], R. YASUDA[2], P. DE CAMILLI[3];
[1]Yale Univ., New Haven, CT; [2]Max Planck Florida Inst. for Neurosci., Jupiter, FL; [3]Depts. Neurosci. and Cell Biology, Kavli Inst. for Neurosci., Yale University, Howard Hughes Med. Inst., New Haven, CT

Abstract: The endoplasmic reticulum (ER) is the site of synthesis of most bilayer lipids. From the ER, newly synthesized membrane lipids are delivered to the plasma membrane via vesicular transport in the secretory pathway. Conversely, insoluble lipid metabolites can return to the ER

for metabolic recycling via the endocytic pathway. This bidirectional traffic requires transit through the Golgi complex and involves at least minutes, but can be much longer in the case of distal neuronal compartments. A direct and more rapid exchange of lipids between the ER and the plasma membrane via lipid transport proteins and independent of membrane traffic also occur. Growing evidence shows that much of this transport occurs via close appositions between the ER and the plasma membrane mediated by protein tethers that contain lipid "harboring" modules. The Extended Synaptotagmins (E-Syts) are a set of three ubiquitously expressed intrinsic ER proteins that function as such tethers. They bind the plasma membrane via their C2 domains, bridging the two membranes in a Ca^{2+} and $PI(4,5)P_2$ regulated manner. Additionally, they have a lipid transport function mediated by their SMP domain. Here we show that GFP-tagged E-Syt constructs localize to soma, axons, dendrites, and dendritic spines of neurons. GFP-E-Syts 2, 3, and fluorescently tagged E-Syt 2/3 heterodimers are constitutively present at ER-plasma membrane contact sites in neurons, however tagged E-Syt1 and E-Syt1/E-Syt2 heterodimers are recruited to these contacts when neurons are stimulated chemically (with glutamate or NMDA) or electrically. Using a FRET-based method, we observed transient GFP-E-Syt recruitment to the plasma membrane in response to local glutamate uncaging. Glutamate uncaging also induced transient migration of the ER into spines that previously did not contain ER. The rapid recruitment of ER-anchored E-Syts following stimulation-induced Ca2+ entry suggests that neuronal activity and plasticity is accompanied by transfer of lipids between the ER and the plasma membrane.

Title: Genetic expression of an active zone peptide to induce cell-specific synaptic depression and to screen for vesicle tethering factors

Authors: *R. J. KITTEL[1], N. SCHOLZ[1], N. EHMANN[1], C. STIGLOHER[2], T. LANGENHAN[1];
[1]Inst. of Physiology, Dept. of Neurophysiol., [2]Div. of Electron Microscopy, Biocenter, Univ. of Wuerzburg, Wuerzburg, Germany

Abstract: Bruchpilot (Brp) is a core protein component of the *Drosophila* active zone (AZ) where it promotes calcium channel clustering to ensure adequate transmitter release probability (Kittel et al., 2006). In addition, the very C-terminal region of Brp supports vesicle tethering to the AZ cytomatrix. In a C-terminally truncated allele, brp^{nude} (lacking the last 17 amino acids), impaired vesicle tethering is accompanied by short-term synaptic depression, impaired sustained transmitter release, and a slowed recovery phase (Hallermann et al., 2010).
We set out to test the hypothesis that neuronal expression of a peptide containing the Brp C-term would deliver a synaptic phenocopy of brp^{nude} by competitively binding the putative vesicular interaction partner(s) of Brp. Our electrophysiological analysis of larval neuromuscular synapses supports this hypothesis and sets the basis for a subsequent *in vivo* screen to identify the interacting protein(s). To this end, a membrane-bound Brp C-term was neuronally expressed to enrich synaptic vesicles at ectopic locations. Different RNAi lines against vesicle-associated proteins were then screened and scored for their ability to revert the ectopic vesicle localisation.

Title: Proteomic screening of GABAergic and glutamatergic neurons isolated by fluorescence activated sorting

Authors: *Z. WEI[1], X. LI[1,2], L. QIN[1], H. YU[1], Z. GAO[1], S. DUAN[1];
[1]Inst. of Neuroscience, Zhejiang Univ., Zhejiang, China; [2]Nantong Univ., Nantong, China

Abstract: Abstract: We established a novel Fluorescence Activated Cell Sorting (FACS) method to purify two major types of neurons in the brain, GABAergic and Glutamatergic neurons. The cleavage of neurons from GAD67-GFP (+/-) on DIV 14-16 were used to investigate the profile of purified GABAergic and glutamatergic neurons samples by Label-free LC-MS/MS. We identified 204 enriched proteins in FACS samples, of which SV2B mainly distributes in glutamatergic Synapse, while SV2C and VAMP1 mainly distribute in GABAergic synapse. Thus, our work indicates that only relatively fewer synaptic proteins are differentially distributed in glutamatergic and GABAergic neurons, which may play important roles in determining differential properties in two types of neurons.

Title: Synaptotagmin1 sorting to synaptic vesicles is probabilistic

Authors: *T. A. SCHIKORSKI[1], D. CRUZ[2];
[1]Univ. Central Del Caribe, Bayamon, PR; [2]Univ. Puerto Rico, San Juan, PR

Abstract: Protein sorting is the very foundation for the genesis of functional distinct cell organelles. At synapses, protein sorting is crucial for the genesis of 'perfect' synaptic vesicles (SV's) that ensure activity-dependent release of neurotransmitter. Many molecular pathways

have been identified that support regulated SV protein sorting but despite these advances, a quantifiable mechanistic model for protein sorting is still missing. In previous studies protein sorting was investigated by exploiting molecular methods followed by high resolution fluorescence imaging. Here, we analysed SV protein sorting on the ultrastructural level by exploiting a new genetically encoded label for electron microscopy with unprecedented high sensitivity, enhanced horseradish peroxidase (eHRP). eHRP is a HRP variant with elevated catalytic activity that is reliably detected in mammalian neurons.
Synaptotagmin 1 is key to activity-dependent SV fusion and failure to sort synaptotagmin 1 will render SV's disfunctional. We tagged synaptotagmin 1 with eHRP and expressed eHRP-synaptotagmin 1 in cultured hippocampal neurons. eHRP-synaptotagmin1 abundantly labeled SVs in many neurons which allowed us to analyse its distribution. eHRP positive SV's spread with no preference in the presynaptic bouton and mixed randomly with the main SV cluster. Also, we did not detect any preferential sorting of eHRP-synaptotagmin1 to one of the functionally defined SV pools and labeled SV's had the same chance as unlabeled SV's to dock at active zones. This data suggested a random distribution of synaptotagmin 1 and not heavily regulated sorting.
To determine the underlying mechanism for synaptotagmin 1's probabilistic distribution we switched to pre-embedding immunogold and measured the synaptotagmin 1 copy number for each SV's at individual presynaptic boutons in cell cultured neurons and *in situ*. Frequency histograms of the copy number per SV were best fitted with a Poisson distribution which is the result of a single probabilistic mechanism that distributes X protein copies to Y SV's. Because the mathematical basis for this process is well known this mechanism can serve as a quantifiable mechanistic model for SV protein 'sorting'. Furthermore, the model can explain molecular distinct SV pools and is useful to estimate protein translation rates in neurons.

Title: Distinct Ca^{2+} dynamics in glutamatergic and aminergic synapses determined by intrinsic neuronal properties independent of synaptic bouton physical dimensions and GCaMP expression levels.

Authors: *X. XING[1], C.-F. WU[2];
[1]Dept. of Biol., Univ. of Iowa, Iowa City, IA; [2]Dept. of Biol., the Univ. of Iowa, Iowa City, IA

Abstract: Our previous work demonstrates distinct stimulus frequency responses of Ca2+ dynamics in glutamatergic tonic type Ib, phasic type Is synapses, and octopaminergic type II synapses in the Drosophila larval neuromuscular junction (NMJ). A fundamental question is whether such distinction is due to intrinsic differences in Ca2+ handling properties of these synaptic boutons, or results from other factors. In principle, the recorded Ca2+ transients can be influenced by bouton physical dimension differences, and variations in the Ca2+ indicator sensitivity, expression level, and cellular localization. In this study, Ca2+ transient amplitude and kinetics from each bouton were individually measured and correlated with bouton size and baseline GCaMP fluorescence intensity. We examined adjacent type Ib, Is and II boutons in the same microscopic field, using cytosolic indicators of different sensitivity (GCaMP1 and 6) as well as membrane-bound GCaMP5. The results show that even though significant variation in bouton sizes exists in each type of synaptic terminals, the maximum fluorescence change (ΔF/F) and the rise and decay kinetics were uniform among boutons along the synaptic terminals, displaying distinct properties characteristic of each specific type. Furthermore, GCaMP expression level may very between synaptic terminals in different larvae, as indicated by basal fluorescence reading without nerve stimulation. However, ΔF/F and rise and decay kinetics remain characteristic of each bouton type. Our data also indicate significantly slower decay kinetics of type II boutons, suggesting a Ca2+ clearance mechanism distinct from type I boutons. Further, examination of hyperexcitability mutations, e.g. eag Sh K+ channel double mutant and bss Na+ channel mutant demonstrated characteristic effect of each mutations, regardless of bouton physical dimension and the GCaMP indicator expression levels. Hyperexcitability enhanced the rise, but not decay, kinetics of Ca2+ transients, reflecting larger Ca2+ influx. Our results show that bouton size variation and choice of the versions of GCaMP indicators do not interfere with the determination of intrinsic synaptic properties of different types of boutons, their characteristic ΔF/F, rise and decay kinetics can be reliably determined with Ca2+ transient measurements from GCaMP signals.

Title: Signaling pathway controlling mitochondria-dependent presynaptic calcium clearance and neurotransmitter release properties at single synapses along cortical axons

Authors: *S.-K. KWON[1], R. SANDO, III[2], T. L. LEWIS, Jr[1], Y. HIRABAYASHI[1], A. MAXIMOV[2], F. POLLEUX[1];
[1]Columbia Univ., New York, NY; [2]The Scripps Res. Inst., La Jolla, CA

Abstract: Individual synapses vary significantly in their neurotransmitter release properties and underlies complex information processing by neural circuits. Presynaptic Ca^{2+} homeostasis plays a critical role in specifying neurotransmitter release properties. Interestingly, several studies revealed that action potential (AP)-evoked presynaptic Ca^{2+} signals differ drastically between individual boutons along the same axons. However, the cellular and molecular pathways regulating Ca^{2+} dynamics in a synapse-specific way are still poorly understood. It has been suggested that mitochondria are involved in presynaptic Ca^{2+} clearance, but the impact on modulation of neurotransmitter release properties varies in different species and neuron subtypes. Also, the signaling pathways regulating presynaptic mitochondrial function in this context are largely unknown. We and others identified that the serine/threonine kinase LKB1 is a master regulator of axon morphogenesis in the mammalian central nervous system. LKB1 is necessary and sufficient for axon formation, and also LKB1 plays an essential role in terminal axon branching *in vivo* through the regulation of presynaptic mitochondrial capture. These latest results raised a central unresolved question regarding the relevance of presynaptic mitochondria in axon morphogenesis. To investigate the role of presynaptic mitochondria, we developed genetically-encoded Ca^{2+} sensors targeted to the mitochondrial matrix (mito-GCaMP5G) or to presynaptic boutons (vGlut1-GCaMP5G) of layer 2/3 cortical pyramidal neurons, and we observed that the presence or absence of mitochondria at presynaptic boutons regulate presynaptic Ca^{2+} levels. In addition, using synaptophysin-pHluorin, we revealed that neurotransmitter release properties at individual presynaptic boutons correlate the presence or absence of mitochondria. Finally, we identified that the LKB1 controls presynaptic Ca^{2+} homeostasis through regulation of the abundance of the mitochondrial calcium uniporter (MCU). Disruption of this signaling pathway leads to increased presynaptic Ca^{2+} accumulation and drastic changes in neurotransmitter release properties, including: (1) increased rate of spontaneous vesicle fusion, (2) augmentation of asynchronous mode of evoked neurotransmitter release, and (3) abrogation of short-term synaptic depression during trains of action potentials (AP). Our results provide novel insights into the cellular and molecular mechanisms whereby mitochondria control neurotransmitter release properties in a synapse-specific way through presynaptic Ca^{2+}clearance.

Title: Quantification of fast presynaptic Ca^{2+} kinetics using non-stationary single compartment model

Authors: Y. TIMOFEEVA[1], D. RUSAKOV[2], *K. E. VOLYNSKI[2];
[1]Dept. of Computer Sci. and Ctr. for Complexity Science, Univ. of Warwick, Coventry, United Kingdom; [2]UCL Inst. of Neurol., London, United Kingdom

Abstract: Fluorescence imaging is an important tool in examining Ca^{2+}-dependent machinery of synaptic transmission. Classically, deriving the kinetics of free Ca^{2+} from the fluorescence recorded inside small presynaptic boutons has relied on singe-compartment models of Ca^{2+} entry, buffering and removal. In many cases, steady-state approximation of Ca^{2+} binding reactions in such a model allows analytical solutions for the Ca^{2+} kinetics in question. However, the fast rate of action potential-driven Ca^{2+} influx is often comparable with the rate of Ca^{2+} buffering inside the presynaptic terminal. In this case, computations that reflect non-stationary changes in the system might be required for obtaining essential information about rapid transients of intracellular free Ca^{2+}. Based on the experimental data we propose an improved procedure to evaluate the underlying presynaptic Ca^{2+} kinetics. We show that in most cases the non-stationary single compartment model provides accurate estimates of action-potential evoked presynaptic Ca^{2+} concentration transients, similar to that obtained with the full three dimensional diffusion model. We also develop a computational tool aimed at stochastic optimisation and cross-validation of the kinetic parameters based on a single set of experimental conditions. The proposed methodology provides robust estimation of Ca^{2+} kinetics even when a priori information about endogenous Ca^{2+} buffering is limited.

Title: Presynaptic calcium dynamics translate bursts of action potential to control the mode of neurotransmitter release at the mossy fiber to CA3 pyramidal cell synapse

Authors: *S. CHAMBERLAND, A. EVSTRATOVA, K. TOTH;
Cell. and Mol. Neurosci., CRULRG, Quebec, QC, Canada

Abstract: Neurons encode information in the number and frequency of action potentials they discharge. Hippocampal granule cells fire infrequently, but discharge bursts of action potential with highly variable frequencies. At the hippocampal mossy fiber to CA3 pyramidal cell synapses, synchronous release, short-term facilitation and asynchronous release actively contribute to the neuronal dialogue. It remains undetermined how giant MF presynaptic terminals translate the number and the frequency of incoming action potentials into specific calcium dynamics to encode distinct modes of release. To investigate this question, we used a combination of electrophysiology and random-access two-photon presynaptic calcium imaging in large MF terminals in acute mouse hippocampal slices. First, we explored the spatiotemporal dynamics of calcium elevations in giant MF terminals. Bursts of 10 APs evoked at 100 Hz increased the intraterminal calcium concentration significantly more than when bursts were evoked at 20 Hz. Interestingly, spatial homogenization of calcium in presynaptic terminals during trains was identical for APs evoked at both frequencies. Next, we observed whether different modes of release could be supported by these specialized calcium dynamics. Repetitive electrical stimulation of mossy fibers (10 stimuli) at 20 Hz and 100 Hz facilitated synchronous EPSCs up to a similar maximum, but facilitation was faster and reached a plateau with 100 Hz stimulation. On the other hand, the frequency of asynchronous release was larger when EPSCs were evoked at 100 Hz than at 20 Hz. Altogether, these results suggest that facilitation of synchronous release is dependent on the number of APs in the trains and is encoded through spatial homogenization of calcium. On the other hand, asynchronous release is dependent on the number of APs and their average frequency, which is encoded in the total peak calcium.

Title: Hemi-fused structure mediates and controls fusion and fission in live cells

Authors: *S. A. VILLARREAL[1], W.-D. ZHAO[1], E. HAMID[1], P. J. WEN[1], E. S. KRYSTOFIAK[2], H.-C. CHIANG[1], B. KACHAR[2], L.-G. WU[1];

Abstract: Membrane fusion and fission are vital to eukaryotes' life. For three decades, it has been proposed that fusion is mediated by fusion between proximal leaflets of two fusing bilayers (hemi-fusion) that produces a hemi-fused structure, followed by fusion between distal leaflets, whereas fission is via hemi-fission, which also produces a hemi-fused structure, followed by full fission. However, owing to the lack of direct observation of hemi-fusion/hemi-fission in live cells, whether hemi-fusion/hemi-fission mediates fusion/fission in live cells is unclear. Whether the hemi-fused structure is the dead end of fusion or serves to prime vesicles for fusion remains unresolved. A competing hypothesis involving the formation of a protein-lined pore has been proposed as the fusion mechanism. With confocal and super-resolution STED microscopy, here we observed the hemi-fused Ω-shaped structure for the first time in live cells (neuroendocrine chromaffin cells). This structure could be generated from either fusion between vesicles and the plasma membrane or fission of fully fused Ω-profiles. Unexpectedly, its transition to full fusion or fission was determined by the competition between fusion and calcium/dynamin-dependent fission mechanisms, and was surprisingly slow (seconds to tens of seconds) in a significant fraction of the events. These results provide evidence missed over the last three decades, proving the hemi-fusion and hemi-fission hypothesis in live cells. Our findings establish a live-cell model of fusion and fission, in which the hemi-fused intermediate is the key structure controlling fusion/fission, as fusion and fission mechanisms compete to determine the transition of the hemi-fused intermediate to fusion or fission.

Title: Activity-dependent movement of synapsin between *Drosophila* motor boutons

Authors: *A. VASIN, M. BYKHOVSKAIA;
Neurol., Wayne State Univ. Sch. of Med., Detroit, MI

Abstract: Synapsin (Syn) is an abundant phosphoprotein that regulates synaptic vesicle clustering, synaptic plasticity, and neuronal development. Our earlier study demonstrated that Syn promotes the activity-dependent outgrowth of new boutons in the *Drosophila* neuromuscular junction (NMJ), and that this mechanism may involve Syn movement and redistribution between synaptic boutons. To investigate this mechanism directly, we generated a *Drosophila* line expressing Syn tagged with a photo-activateable mCherry marker. Employing this line, we selectively activated the mCherry tag within individual boutons and tracked synapsin movement along the NMJ for a period of one hour. We found that Syn did move between synaptic boutons, and that this movement depended on the neuronal activity. At rest, we were able to observed Syn movement towards neighboring boutons in some of the preparations. In contrast, high frequency (10 or 30 Hz for 30 min) stimulation of the nerve, as well as high K^+ depolarizations, produced Syn movement over the NMJ length of 10-15 μm. These stimulation paradigms typically included Syn redistribution over 3-5 synaptic boutons. Interestingly, the movement continued after the end of the stimulation and during the entire time period analyzed (1 hour). These results suggest a novel Syn function in the mechanisms of signaling and trafficking between synaptic boutons, which can be triggered by intense neuronal activity.

Title: Monitoring vesicle dynamics in gaba-depleted hippocampal neurons using vgat-phluorin.

Authors: *L. BONET, S. SUPPLISSON;
IBENS, Paris, France

Abstract: There is still no comprehensive understanding of the molecular organization and mechanisms that regulate the filling of GABA-containing vesicles during their continuous recycling at inhibitory terminals. In hippocampal neuronal cultures, electrophysiological recordings in pairs and FM5-95 uptakes show a progressive reduction in the pool of recycling vesicles when GABAergic neurons run out of transmitter, whereas restoring GABA supply in GABA-depleted terminals reinstates normal vesicle cycling and filling (Wang et al., Neuron 80:143, 2013).
Here, we used VGAT-pHluorin for monitoring vesicle recycling during long trains of action potentials. VGAT (also named VIAAT) is the vesicular transporter shared by all inhibitory interneurons with its C-terminus located inside the vesicle lumen. In resting condition, the fluorescence of the pH-sensitive GFP (super ecliptic pHluorin) fused to the VGAT C-terminus is quenched by the acidic vesicular pH (Santos et al., J Neurosci 33:10634, 2013).
We expressed VGAT-pHluorin in neuronal cultures derived from rat hippocampus, and performed electrophysiological recordings and imaging ≥7 days post transfection. Brief application of NH4 reveals a punctate distribution of VGAT-pHluorin in axonal varicosities with a high signal-to-noise ratio (x2 to 4) using a high-resolution sCMOS camera. Extracellular acidification with MES (2-(N-morpholino) ethanesulfonic acid) shows low background expression of VGAT-pHluorin at the plasma membrane. Trains of action potentials at 20Hz evoked by electrical stimulation of the transfected neuron activate the same varicosities as NH4 but with lower intensity, as expected if only a fraction of the vesicles undergo exocytosis.
Using low transfection rate, it is possible to identify and whole-cell patch putative pairs of synaptically connected neurons. Surprisingly, evoked post synaptic currents recorded in the presence of NBQX 2µM and MK801 5µM were inhibitory in all pairs tested, blocked by SR 10µM, suggesting that overexpression of VGAT-pHluorin might be toxic in excitatory neurons.

The large presynaptic response evoked with 300 APs at 20 Hz showed modest steady release of GABA, presumably because of the large synaptic depression at this frequency. This suggests that vesicles if recycled, could not be fully filled with GABA. In contrast, we observed a steady but lower fluorescent signal during 4Hz stimulation as expected when endocytosis compensates for exocytosis.
These results confirm that VGAT-pHluorin is a useful probe to monitor vesicle recycling in GABAergic interneurons.

Title: *In vivo* time lapse imaging of axonal dense core vesicle trafficking in anaesthesized and awake mice

Authors: *J. KNABBE[1], J. NASSAL[1], H. HORSTMANN[1], M. VERHAGE[2], T. KUNER[1]; [1]Inst. of Functional Neuroanatomy, Heidelberg, Germany; [2]Dept. of Functional Genomics, Ctr. for Neurogenomics and Cognitive Res., Amsterdam, Netherlands

Abstract: Dense core vesicles (DCV) are large, electron-dense vesicles designed to transport a variety of cargo molecules, including neuropeptides or neurotrophins, from their site of production at the neuronal soma towards their respective release sites in dendrites or axons. Trafficking and movement characteristics of DCVs have been typically investigated in chromaffin cells or primary cell culture models. Yet, DCV trafficking characteristics and their responsivity to physiological release signals could differ fundamentally in the mammalian brain *in vivo* due to the densely packed tissue neuropil, neuronal connectivity, neuron-glial interactions or different functional brain states. In this study, we used multiphoton-*in*-*vivo*-imaging to visualize DCV trafficking in the central nervous system in anaesthesized or awake mice through a chronically implanted cranial window. Viral co-expression of live fluorescent DCV-markers and axonal markers in thalamic projection neurons allowed us to specifically visualize axonal projections from the thalamus to upper layers of the cortex. Ultrastructural features of the labeled vesicles were assessed using electron-microscopy and photooxidation of fluorescent DCV- and axon markers. Taking advantage of semiautomated and automated tracking approaches we were able to analyze the movement of hundreds of vesicles in individual axons of different animals. These data for the first time reveal speed, directionality and number of moving DCVs and their

movement characteristics at axonal en passant boutons *in vivo* in awake and anaesthesized mice. This approach will enable future studies of the physiological mechanisms triggering DCV cargo-release and studies examining DCV trafficking in pathophysiological situations potentially linked to defects in DCV trafficking, such as neurodegenerative disorders and the aging brain.

Title: Dynamics of synaptic vesicle protein after single vesicle exocytosis at a hippocampal presynaptic active zone recorded by a novel live-cell imaging method

Authors: *J. FUNAHASHI, H. TANAKA, T. HIRANO;
Dept. of Biophys., Grad. Sch. of Sci., Kyoto Univ., Kyoto, Japan

Abstract: In presynaptic terminals neurotransmitter is repetitively released depending on patterns of action potential firing. To support multiple rounds of release, synaptic vesicles and their proteins need to be recycled efficiently. However, molecular mechanisms to regenerate synaptic vesicles are not fully elucidated. Especially, how synaptic vesicle proteins are retrieved after exocytosis remains unclear. To address this issue, we have developed a novel live-cell imaging method and aimed to monitor dynamics of synaptic vesicle proteins after single vesicle exocytosis at a hippocampal presynaptic active zone. We used total internal reflection fluorescence microscopy (TIRFM) that allows observation of fluorescent molecules with a high signal-to-noise ratio by limiting the depth of excitation field to approximately 100 nm. To visualize fluorescent molecules at active zones with TIRFM, we induced active zone formation on the glass surface. We coated cover glass with a synaptic adhesion molecule Neuroligin (postsynaptic membrane protein that can induce presynaptic differentiation). Afterward, we cultured rat hippocampal neurons on Neuroligin-coated glass. To examine whether active zones are formed on the glass surface, we transfected EGFP and TagRFPt-CAST to neurons. TagRFPt-CAST is a fusion protein of a red fluorescent protein TagRFPt and an active zone scaffold protein CAST. Many TagRFPt-CAST positive axonal areas were observed with TIRFM, suggesting presynaptic structures were formed directly on the Neuroligin-coated glass. Then, we

transfected TagRFPt-CAST and SypHy (synaptic vesicle protein Synaptophysin tagged with a pH-sensitive fluorescent protein Super Ecliptic pHluorin) to neurons. Whereas SypHy does not show fluorescence in acidic synaptic vesicles, it becomes brighter upon exocytosis. We applied an electrical field stimulation to trigger exocytosis and recorded the SypHy signal around a CAST-labeled active zone. An increase in the SypHy signal at the active zone coincident with the stimulation, was observed in about 10% of trials. We presumed that such an event corresponded to exocytosis of single synaptic vesicles. The SypHy signal decreased within about 100 ms in most cases. The time course of SypHy signal decrease could be classified into two patterns. In one pattern the SypHy signal spread and decayed, suggesting Synaptophysin diffused out from the release site at the active zone. In another pattern the SypHy signal rapidly disappeared without signal spread, which might correspond to kiss-and-run exo-endocytosis.

Title: Rapid and spatially-confined PI(4,5)P_2 manipulations by optogenetic approaches regulate vesicle docking and secretion.

Authors: ***C. JI**, F. FAN, X. LOU;
Univ. of Wisconsin-Madison, Madison, WI

Abstract: Phosphoinositides in the plasma membrane (PM) regulate vesicle trafficking and secretion. As a key PM determinant phospholipid, PI(4,5)P_2 is required for both hormone secretion and transmitter release. However, the molecular and cellular mechanism in which PI(4,5)P_2 directly regulates vesicle trafficking and secretion remains poorly understood. The available approaches, such as genetic perturbations or pharmacological inhibitors, often suffer from chronic compensation or off-target and complicate the interpretations of data. Here,

utilizing the latest optogenetic tools based on the blue light-inducible molecule demonization and translocation, we developed a novel approach to rapidly and specifically manipulate $PI(4,5)P_2$ levels in the PM. We achieved rapid and efficient decrease of the $PI(4,5)P_2$ levels within several seconds in INS-1 cells, a secretory cell model that is widely used to study the regulated insulin secretion. Combing with TIRF imaging, we characterize the properties of the light-induced $PI(4,5)P_2$ level changes and their impacts on different steps of insulin granule trafficking. A global decrease of $PI(4,5)P_2$ level enhances insulin granule dynamics, inhibits the evoked increase in intracellular Ca^{2+} concentrations, and impairs secretion. To mimic the physiological condition where $PI(4,5)P_2$ often changes locally rather globally, we have designed an approach to selectively decrease the local $PI(4,5)P_2$ levels at vesicle docking sites on the PM. Preliminary data from this approach reveals a selective defect in vesicle docking, without a detectable change in global $PI(4,5)P_2$ levels. This approach provides a new step toward understanding the lipid signaling in vesicle trafficking in secretory cells; it can be adapted for the study of other phosphoinositides in cell signaling. Our data suggest that $PI(4,5)P_2$ mediated vesicle docking might be a rate-limiting step of the regulated secretion under physiological conditions.

Title: Spike-timing dependent plasticity in the long latency stretch reflex following paired stimulation from a wearable electronic device

Authors: *K. FOYSAL, F. DE CARVALHO, S. BAKER;
Inst. of Neurosci., Newcastle Univ., Newcastle upon Tyne, United Kingdom

Abstract: The reticulospinal tract contributes to control hand and arm movements in primates and plays a key role in functional recovery after corticospinal lesion. Here we tested the ability of non-invasive paired stimulation delivered by a wearable electronic device to produce plastic changes in reticulospinal output. We first recorded the long-latency stretch reflex (LLSR) from

elbow flexor muscles of healthy adult human subjects following an extensor perturbation as a putative measure of reticulospinal output. Subjects were then fitted with the portable device which delivered auditory click stimuli through an earpiece, and electrical stimuli around motor threshold to the biceps muscle via surface electrodes. Auditory clicks are known to generate action potential bursts in reticulospinal neurons, which are also activated by peripheral afferents. We tested four paradigms: biceps stimulus 10 ms before click (Bi-10ms-C); click 25 ms before biceps (C-25ms-Bi); click alone (C only); biceps alone (Bi only). Average stimulus rate was 0.67 Hz. Subjects left the laboratory wearing the device, and performed normal daytime activities. Around 7 hours later, they returned and stretch reflexes were re-measured to compare with the measurements taken before. The LLSR was significantly enhanced in the biceps muscle (on average by 49%) after the Bi-10ms-C paradigm, but suppressed for C-25ms-Bi (by 36%). For the same muscle, Bi-only and C-only did not induce any change in the LLSR. No changes occurred in the LLSR for the brachioradialis muscle while testing any of the four paradigms.
We conclude that paired stimulation with precisely adjusted order and time intervals was able to strengthen or weaken LLSR pathways selectively for the stimulated muscle. This result is consistent with spike-timing dependent plasticity and may reflect changes in reticulospinal output. This is the first demonstration that such circuits may be modifiable via paired-pulse methods, and could open up new possibilities in motor systems neuroscience and rehabilitation.

Title: The role of local excitatory networks in the lateral amygdala in emotional memory learning

Authors: *M. ABATIS[1], R. NIU[1], R. PERIN[2], H. MARKRAM[2], H. BITO[3], R. STOOP[1]; [1]Dept. of Psychiatry, CHUV, Prilly, Switzerland; [2]BMI, EPFL, Lausanne, Switzerland; [3]Dept. of Neurochemistry, Univ. of Tokyo, Tokyo, Japan

Abstract: Introduction: Fear conditioning combines an unconditioned stimulus with a conditioned stimulus (CS) so that the CS alone can subsequently elicit fear-related responses. While the convergence of signals onto single lateral amygdala (LA) neurons has been

extensively studied, little is known about the role of connections between LA neurons in threat memory encoding. Indeed, recent findings in the hippocampal CA3 highlight the role of recurrent networks in memory encoding (Rajasethupathy et al., Nature, 2015), prompting further investigation.
Aims: We hypothesized that threat-related signals are re-integrated in the LA through local neuronal assemblies. To address this, we aimed to characterize the LA's network organization, including connectivity among memory-participating neurons.
Methods: We used whole-cell patch-clamp recordings to simultaneously access up to 12 neurons at a time. The connectivity of over 563 neurons was assessed by delivering, successively, trains of 8 pulses at 20 Hz and monitoring for induced post-synaptic potentials. Neuronal memory-recruitment was assessed by expressing a destabilized GFP under an enhanced Arc promoter, after threat memory recall.
Results: We observed ~2% connectivity biased towards close-proximity neurons. Analysis of the peak excitatory post-synaptic current amplitudes by simple binomial analysis suggested 1-5 release sites, with a quantal size of 10±3 pA and probability of release of ~0.5 ± 0.2 (±SD).
To better understand how this network could encode fearful memories, we performed a spike-timing-dependent plasticity protocol which resulted in a 30% increase in amplitude for the first excitatory post-synaptic potential (EPSP) of the stimulus train, while average EPSP amplitude was unchanged, suggesting a redistribution of synaptic efficacy.
Finally, we assessed connectivity among neurons participating in the recall of a threat memory trace. Recruited neurons had greater connectivity (4%), higher EPSP amplitude (1.4±0.1 mV) and higher probability to observe an EPSP (0.5±0.04 %) compared to controls (2%, 0.9±0.1mV and 0.4±0.01%, respectively; ±s.e.m.). This suggests that either stronger and more numerous connections enhance local network excitability and favor memory recruitment or that the observed changes result from memory recruitment.
Conclusion: The LA network follows a "small-world" network organization, with memory-recruited neurons forming stronger and more numerous connections. This suggest either that enhanced local network excitability favors memory recruitment or that memory recruitment increases connectivity, to be determined by future experiments.

Title: Postsynaptic calcium dynamics associated with bidirectional plasticity of NMDA receptor-mediated transmission

Authors: S. LUTZU[1], *K. ALVINA[2], P. CASTILLO[1];
[2]Neurosci., [1]Albert Einstein Col. of Med., Bronx, NY

Abstract: NMDA receptors (NMDARs) mediate fast excitatory transmission and are crucial for normal neural circuit development and cognitive processes such as learning and memory. While classically considered triggers of long-term plasticity (LTP/LTD) of AMPA receptors (AMPARs), NMDARs themselves can be dynamically regulated by activity in a long-term manner. NMDAR plasticity (e.g. NMDAR-LTP/LTD) has been described at several key brain areas where it strongly impacts spike transfer and could contribute significantly to learning and memory; however, very little is known about its molecular basis. Hippocampal mossy fiber-to-CA3 pyramidal cells (mf-CA3) synapses express robust bidirectional, burst timing-dependent NMDAR plasticity (BTD-NMDAR-LTP/LTD), which can be easily elicited with physiologically-relevant, coincident pre/postsynaptic burst activity. Both BTD-NMDAR LTP and LTD depend on postsynaptic calcium rise but the calcium sources differ, suggesting that different calcium dynamics could determine the bidirectionality of NMDAR plasticity. To test this hypothesis we combined electrophysiology with 2-photon laser microscopy in acute rat hippocampal slices in order to measure postsynaptic Ca^{2+} dynamics (i.e. calcium transients or CaTs) during the induction of BTD-NMDAR-LTP/LTD. We compared CaTs at thorny excrescences (TEs, the postsynaptic target of mf-CA3 synapses) with those generated at simple dendritic spines receiving associational/commissural (A/C) synapses which do not express NMDAR plasticity. We found that burst-induced postsynaptic CaTs associated with basal synaptic transmission at both TE and A/C spines are largely mediated by NMDARs, whereas CaTs evoked by back propagating action potentials are mostly mediated by L-type voltage-gated calcium channels. Intracellular stores and group-I metabotropic glutamate receptors (I-mGluRs) were also found to contribute to TE CaTs. Furthermore, CaTs were significantly larger during the induction of BTD-NMDAR-LTP than NMDAR-LTD, a difference that was also observed by direct postsynaptic activation using glutamate uncaging. Lastly, TE CaTs associated with BTD-NMDAR-LTP and LTD were differentially affected by pharmacological blockade of distinct Ca^{2+} sources. Together, our findings strongly suggest that the sign of NMDAR plasticity observed at mf-CA3 synapses (i.e. LTP/LTD) is critically determined by specific postsynaptic Ca^{2+} signals.

Title: Paired transspinal and transcortical associative stimulation modulates human spinal motor output

Authors: *M. KNIKOU, D. SANTORA, L. DIXON, M. M. IBRAHIM;
The Grad. Ctr., City Univ. of New York, Staten Island, NY

Abstract: The neuronal networks of the human spinal cord translate inputs from multimodal peripheral receptors and descending motor tracts, and are prone to modulation and sustained plasticity. Paired associative stimulation (PAS) of presynaptic and postsynaptic cells produces spike-timing-dependent plasticity via synaptic mechanisms. However, the effects of pairing transspinal and transcortical stimulation on human spinal motor pathways are not known. In this study, we delivered paired transspinal and transcortical stimuli for 40-min at an interstimulus interval that TMS was delivered after (transspinal-transcortical PAS) or before (transcortical-transspinal PAS) transspinal stimulation in 14 healthy human subjects. In the transspinal-transcortical PAS, the transspinal stimulation served as the presynaptic input to cortical neurons. In the transcortical-transspinal PAS, transcortical stimulation served as the presynaptic input to spinal neurons. Spinal motor output was assessed via the transspinal evoked potentials (TEPs) recruitment curves and the amount of postactivation of TEPs. We found that PAS-induced plasticity at a spinal level can be achieved with pairing transspinal and transcortical stimulation. The effects depended on the timing between the two inputs since transcortical-transspinal PAS decreased and transspinal-transcortical had the opposite effect in the amplitude of knee/ankle TEPs recorded from both limbs at 0.2 Hz and at the same stimulation intensities before and after PAS. In contrast, from the TEPs recruitment curves we found that the amplitude of most ankle TEPs was decreased after transcortical-transspinal PAS and after transspinal-transcortical PAS. The decreased amplitude of TEPs coincided with increased gain of the spinal motor output system only after transcortical-transspinal PAS and not after transspinal-transcortical PAS. These findings provide evidence towards a new paradigm to alter spinal motor output in humans.

Title: Optimal learning with redundant synaptic connections

Authors: *N. HIRATANI[1,2], T. FUKAI[1,3];
[1]RIKEN Brain Sci. Inst., Saitama, Japan; [2]The Univ. of Tokyo, Kashiwa, Japan; [3]JST CREST, Tokyo, Japan

Abstract: Recent experimental studies suggest that, in cortical microcircuits of the mammalian brain, the majority of neuron-to-neuron connections are realized by multiple synapses. For instance, in the barrel cortex of juvenile mice, mean number of synapses per connection is estimated to be around 10. However, little is known on the functional benefit of having such redundant synaptic connections. Here, we show that redundant synaptic connections enable near-optimal learning in cooperation with synaptic rewiring. By constructing a simple dendritic neuron model, we demonstrate that, in multi-synaptic connections, synaptic plasticity approximates a particle-filtering algorithm, and wiring plasticity corresponds to its resampling process. The derived synaptic plasticity rule reconciles with dendritic position dependence of spike-timing-dependent plasticity observed in previous experiments. In particular, our study reveals a functional merit of anti-Hebbian plasticity at distal synapses. The model also explains why two synapses projected to different dendritic branches from the same axon seldom show spine-size correlation, while those on the same branch exhibit tight size correlation. The proposed framework is extensible for a detailed single neuron model, and also applicable to recurrent circuit models. In conclusion, our study provides a novel conceptual framework for synaptic plasticity and rewiring by focusing on redundancy in synaptic connections.

Title: Anti-Hebbian learning of optimal homeostatic IPSG amplitude and decay time

Authors: *J. K. KIM, C. D. FIORILLO;
Bio and Brain Engin., Korea Advanced Inst. of Sci. and Technol., Daejeon, Korea, Republic of

Abstract: For spikes to be sensitive to synaptic excitation requires properly balanced inhibition. We previously proposed that perfect homeostatic balance is achieved when the peak of an excitatory postsynaptic potential (EPSP) reaches exactly to spike threshold, so that the slightest variation in the amplitude of synaptic excitation determines whether or not a spike is generated (Fiorillo et al., 2014). With this as the homeostatic ideal, we used computer simulations and a measure of 'distance from optimality' to find the optimal amplitude and decay time of inhibitory postsynaptic conductance (IPSG) across a range of excitatory postsynaptic conductance (EPSG) frequencies of 5 to 800 Hz (with delay from EPSG to IPSG onset of 1.0 ms). With increasing frequency, the optimal ratio of IPSG to EPSG peak amplitude increased from 0.4 to 3.7, and optimal IPSG decay time constants decreased from 24 to 1.8 ms. According to theory, synapses and ion channel subtypes that are near to optimal in maintaining homeostasis can be selected through anti-Hebbian, spike-timing dependent learning rules (Fiorillo, 2008; Fiorillo et al., 2014). We tested this using NEURON software to create a single-compartment model with 9 synapses, each having a distinct decay time constant for synaptic inhibition (1.5 to 50 ms). Once learning resulted in stable synaptic weights, both IPSG amplitude and decay time closely matched those found to be optimal. To compare our estimates of optimality to experimental observations, we estimated typical EPSG input rates of 5 to 600 Hz across 19 types of neurons, and we found measures of IPSG decay time constants for each type of neuron (1 to 50 ms). We compared our theoretically optimal relation between decay time and EPSG input rate to the experimentally measured relation and found a highly significant quantitative match. Thus the theory of 'predictive homeostasis' appears able to predict and explain IPSG decay time. It also provides a means by which a neuron could learn IPSG decay times that are optimal with respect to the specific pattern of EPSG that it receives.

Title: Activity-dependent anti-Hebbian glutamatergic spike-timing dependent plasticity within the lateral habenula

Authors: *L. D. LANGLOIS[1], F. NUGENT[2];
[1]Pharmacol., Uniformed Services Univ. of the Hlth. Scienc, Bethesda, MD; [2]Pharmacol., Uniformed Services Univ. of the Hlth. Sci., Bethesda, MD

Abstract: The lateral habenula (LHb) is an epithalamic structure involved in brain reward processes by providing negative reward signals to brain dopamine and serotonin systems. Hyperactivity of LHb neurons has been associated with exposure to addictive drugs and depression. One of the main risk factors for such mental disorders is early life stress-induced dysregulation of midbrain dopamine signaling. Our recent work has linked epigenetic modifications and metaplasticity within the ventral tegmental area (VTA) dopamine system to a single episode of maternal deprivation (MD) as an early life stressor. We have now extended our studies to the LHb and found that LHb neurons of MD rats (P21-P30) are also hyperexcitable. To address whether MD triggers changes in LHb excitability and DA signaling through induction of metaplasticity in the LHb, we started to investigate the induction of glutamatergic spike-timing dependent plasticity (STDP) of LHb neurons in response to near-coincident pre- and post-synaptic activities. Coincident pre and postsynaptic firing is required for glutamatergic STDP of LHb neurons as pre or postsynaptic activity alone is insufficient to induce plasticity. Neither neurons displaying silent, tonic nor irregular firing pattern expressed bidirectional STDP in response to all STDP induction protocols with different time intervals tested so far. Tonic firing neurons showed long-term potentiation (LTP), regardless of spike-timing order. Instead, in response to our spike-timing protocols, quiet and irregularly firing neurons either expressed LTD or no plasticity. This suggests that LHb neurons display activity-dependent anti-Hebbian STDP. Interestingly, the basal excitability of LHb neurons may reliably predict the direction of plasticity in STDP of the LHb. We will continue to characterize STDP and evaluate the effects of MD on STDP of LHb since MD-induced synaptic abnormalities and alteration in dopamine signaling from the VTA may be downstream to metaplastic changes of STDP within the LHb.

Title: Identification of a functional spike-timing-dependent plasticity rule from ensemble hippocampal spiking activity with generalized multilinear modeling

Authors: *B. S. ROBINSON[1], D. SONG[1], R. E. HAMPSON[2], S. A. DEADWYLER[2], T. W. BERGER[1];

Abstract: The degree to which spike-timing-dependent plasticity (STDP) underlies fluctuations in synaptic strength during behavior is not well understood. One reason for this is that measuring how synaptic strength is influenced by spontaneously occurring behavioral spiking activity is experimentally challenging. Here, nonlinear dynamical modeling is used to identify functional connectivity strength between neurons by quantifying the conditional firing probability of an output neuron's spiking activity given an input neuron spiking event. This nonlinear dynamical model additionally identifies an STDP rule that characterizes how the relative input-output neuron spike timing relates to fluctuations in functional connectivity strength over time. Basis function expansion and generalized multilinear modeling are used to formulate and identify STDP model functions from recorded spiking activity in CA3 and CA1 hippocampal regions. The identified STDP models are able to capture weight fluctuations in functional connectivity strength for certain behavioral sessions. We also investigate how several sets of assumptions in STDP rule formation vary in ability to capture the dynamics of the observed spiking activity, such as weight-dependence and incorporation of triplets. The identified plasticity rules provide insights into how an STDP rule may lead to fluctuations in functional connectivity strength observed during behavior.

Title: Potential roles of intracellular calcium dynamics regulated by calcium stores for spatial association of synaptic plasticity

Authors: D. FUTAGI, *K. KITANO;
Ritsumeikan Univ., Kusatsu, Japan

Abstract: Many studies have reported that the strength of a synapse undergoes a change depending on firing rates or spike timings of pre- and postsynaptic neurons. Furthermore, recent findings showed that synaptic plasticity induced at a synapse is accompanied by changes at the adjacent sites, namely, hetero-synaptic plasticity. It is strongly suggested that this collective synaptic plasticity should play an important role for forming and maintaining synaptic connectivity for neural functions whereas the mechanism that associates homo-synaptic plasticity with hetero-synaptic plasticity is not much known. Because spatiotemporal intracellular calcium dynamics mediated by calcium stores is likely to underlie the spatial association between the homo- and hetero-synaptic plasticity, it should be an important issue to reveal how such calcium dynamics is involved in the collective synaptic plasticity. In the present study, we studied a potential role of the calcium dynamics by numerical simulation of a computational model. Our model was built by combining a multi-compartmental neuronal model with a model of intracellular calcium dynamics, which enable us to see how a calcium increase triggered by pre- and/or postsynaptic spikes is regulated by the store dynamics. We here considered two different types of receptors on calcium stores that regulate calcium release: ryanodine receptors (RyRs) and inositol 1,4,5-triphosphate receptors (IP3Rs). Model simulations showed these receptors differently function; RyR-mediated calcium increase was independent of pre- and postsynaptic spike timings and the distance from an induction site whereas IP3R-mediated one depended on them. In particular, IP3R could shape the temporal window known for the spike-timing-dependent plasticity. Thus, our results suggested that calcium release from the calcium stores would be involved in the spatial association of synaptic plasticity and the two different types of receptors could contribute to it differently.

Title: Cholinergic modulation on LTD in rat hippocampal network

Authors: *E. SUGISAKI[1], Y. FUKUSHIMA[2], S. FUJII[3], N. NAKAJIMA[1], T. AIHARA[1]; [1]Tamagawa Univ. Grad. Sch. of Engin., Tokyo, Japan; [2]Kawasaki Univ., Kurashiki, Japan; [3]Yamagata Univ., Yamagata, Japan

Abstract: Synaptic plasticity is a fundamental property of learning and memory. The spike timing-dependent plasticity (STDP) protocol is one of the various stimulation that can induce synaptic plasticity. In interneuron-activated network, long-term potentiation (LTP) and long-term depression (LTD) can be observed by positive timing protocol (EPSP then BPAP) application depending on the relative timing of spikes, while only LTD can be induced by negative timing protocol (BPAP then EPSP) application. In a meantime, acetylcholine (ACh) is known as a crucial modulator for sensory inputs. The cholinergic neurons are projecting to pyramidal neurons and interneurons, and muscarinic ACh receptors (mAChR) and nicotinic ACh receptors (nAChR) are widely distributed in hippocampus. In the previous studies, the effect of each AChR activation on synaptic plasticity was investigated, however the combined effect of AChR activation is still unclear.In order to evaluate the combined influence of mAChRs and nAChRs on pyramidal neurons and interneurons on STDP in interneuron-activated network, patch clamp recording was made in the soma of pyramidal neuron applying a positive or negative timing protocol in the presence or absence of eserine (a cholinesterase inhibitor) using rat hippocampal slices. Moreover, the dependence of AChR-type specificity on STDP was investigated by the application of atropine or mecamylamine, mAChR or nAChR blocker respectively.As the results in interneuron-activated network, LTD observed by the positive timing protocol was switched to LTP, and the LTD by negative timing protocol was shifted toward potentiation in the presence of eserine. If nAChR and interneuron were prevented for only mAChR on pyramidal neuron to be activated, the larger STDP than that of the control condition, but smaller than that of the eserine application was observed at positive or negative timing protocol in interneuron-blocked network. On the other hand, when only nAChR on pyramidal neuron was activated, smaller STDP than the one of mAChR activation on pyramidal neuron was induced. Next in interneuron-activated network, the activation of mAChR on interneuron switched the STDP direction into LTD in the

absence of nAChR. Meanwhile, the activation of nAChR on interneuron did not change the direction of STDP. These results suggest that the STDP is shifted toward potentiation in the presence of ACh by co-activating mAChR and nAChR not only on pyramidal neuron but also on interneuron. Furthermore, the direction of STDP is decided by the combined activation of mAChR on pyramidal neuron and interneuron, while nAChRs sensitively fine-tune the magnitude of STDP.

Title: Developmental profile of spike timing-dependent plasticity at CA3-CA1 synapses of mouse hippocampus

Authors: ***A. RODRIGUEZ-MORENO**, Y. ANDRADE-TALAVERA, P. DUQUE-FERIA; Univ. Pablo De Olavide, Seville, Spain

Abstract: Spike Timing-Dependent Plasticity (STDP) is a strong candidate for a synaptic mechanism involved in development and in learning and memory. The goal of this work was to determine the developmental profile of STDP in the hippocampus. We performed experiments in the CA1 region of hippocampal slices prepared from P4-P112 mice using the whole-cell configuration of the patch-clamp technique. To induce t-LTP, a pre-post pairing protocol (with the presynaptic activity occurring 5 ms before a postsynaptic action potential) was applied after a stable EPSP baseline period of 10 min. To induce tLTD, a post-pre pairing protocol (with the presynaptic activity occurring 18 ms after a postsynaptic action potential) was applied. We found that a pre-post pairing protocol induced a robust t-LTP after the first postnatal week and at P21-P28, P65-P79 and P103-P112 mice. A post-before-pre pairing protocol was able to induce a significant depression at P8-P14 (72 ± 3%, n = 7) as well as P15-P21. However, this protocol was unable to induce t-LTD in P22-P42 mice. These results suggest that spike timing-dependent

depression emerges during the first postnatal week and disappears in the adulthood and that t-LTP emerges during the second postnatal week and persists in the adulthood at CA3-CA1 synapses.

Title: Complex circuits from simple learning rules

Authors: *J. OLSON, G. KREIMAN;
Harvard Univ., Cambridge, MA

Abstract: Cortical circuits follow specific canonical connectivity patterns that are important for local computations. These canonical motifs have been described throughout cortex. What are the learning rules governing the cortical wiring instantiating canonical circuits? While the broad strokes of circuit development generally rely upon molecular cues dictating the general targets of neuronal migration as well as the direction of dendritic and axonal growth patterns, the refinement and specification of circuits depend upon neural activity and plasticity mechanisms. Here we ask whether simple learning rules alone can give rise to such complex circuitry. We focus on spike timing dependent plasticity (STDP), where a synapse is strengthened or weakened based on the relative timing of spiking between the pre- and post- synaptic neurons. We use a computational model to show how a combination of two different variations of STDP, classical STDP (cSTDP) and reverse STDP (rSTDP), can generate canonical circuits. Starting from all-to-all connectivity, the model dynamically converges onto a canonical circuit resembling the cortical columnar circuit described in macaques by Lund (Lund, 2002) and in cats by Douglas and Martin (Douglas and Martin, 2004). The configuration of STDP rules necessary for the model to converge to the canonical circuit is consistent with experimental observations. The target circuit motifs arise if and only if synapses from layer 2/3 to layer 5/6 follow either cSTDP or rSTDP as reported by Letzkus et. al. (Letzkus et. al. 2006) and synapses from layer 4 to layer

2/3 follow only cSTDP as reported by Feldman (Feldman 2000). Our results make further predictions about the STDP rules to be expected among different cortical layers. In summary, the current model demonstrates that simple activity-dependent plasticity rules can give rise to the type of complex connectivity patterns that are pervasive throughout neocortex and provides a principled path to explain connectomics data.

Title: Experience-dependent regulation of spike-timing dependent plasticity of inhibition in auditory cortex

Authors: *E. D. VICKERS[1], R. SCHNEGGENBURGER[2];
[2]BMI, [1]EPFL, Lausanne, Switzerland

Abstract: In the input layers of tonotopically organized auditory cortex (A1), feedforward inhibition from parvalbumin interneurons (PV INs) onto principal cells (PC) plays a critical role in controlling the window of temporal integration of thalamic inputs. In this feedforward circuit, the temporal relationship between action potentials (APs) of PV INs and PCs is precise; spike-timing dependent plasticity (STDP) of inhibition might therefore allow for activity-dependent regulation of PC integration and AP generation. Here we characterized STDP of PV IN GABAergic output synapses in the input layer of A1 by making paired whole-cell recordings between genetically identified PV INs and PCs, initially at P15 - P22. The STDP induction protocol consisted of 50 pairings of single pre- and postsynaptic APs at 0.2 Hz. We observed robust bi-directional STDP of inhibition. Long-term potentiation of inhibition (iLTP; ~55%) followed post-then-pre AP pairings (dt ~ -5 ms), and long-term depression of inhibition (iLTD; ~30%) followed pre-then-post AP pairings (dt ~ +5 ms). Variance-mean analysis suggested that iLTP has a presynaptic locus of expression. iLTP required the activation of L-type Ca2+ channels and localized postsynaptic Ca2+ transients (sensitivity to BAPTA); pharmacology showed a role for BDNF signaling via TrkB receptors. iLTP is therefore likely mediated by retrograde release of BDNF from PCs. iLTD also depended on TrkB signaling, but had a post-synaptic locus of expression.
We found that iLTD in young mice (P15-22) was transformed into iLTP with postnatal development (P28-31). This suggested that iLTD could be involved in experience-dependent A1

tonotopic map plasticity during a critical period, the closure of which coincides with a changed learning rule at inhibitory synpases. We developed an ex vivo slice approach, using "tetTag" mice, to visualize and record from neurons in A1 of mice that underwent 3 days (P11-14) of sound exposure (30 kHz, ~70 dB). This was followed by a brief "labeling" session (60 minutes at ~85 dB). 2-photon imaging of cFos promoter-driven tdTomato expression revealed sound-dependent tonotopic band labeling. We performed paired recordings between PV INs and tdt+ PCs (that is, PCs that were strongly activated by the 30 kHz sound labeling) and found that critical period sound exposure increased unitary IPSG amplitudes and converted iLTD into iLTP at P18 - P20. Taken together our work shows that bi-directional, BDNF-dependent STDP of inhibition is regulated by both experience and development. We hypothesize that spike-timing dependent iLTD is permissive for developmental plasticity of frequency tuning in A1.

Title: Spike-timing-dependent plasticity for short-term memory and long-term memory

Authors: *Y. PARK[1], W. CHOI[1,2], S.-B. PAIK[1,2];
[1]Bio and brain engineering, KAIST, Daejeon, Korea, Republic of; [2]Program of Brain and Cognitive Engineering, KAIST, Daejeon, Korea, Republic of

Abstract: Spike-timing-dependent plasticity (STDP) is a commonly observed learning rule that precisely modulates synaptic strength according to the temporal coherence of pre-and postsynaptic spike timings (Bi and Poo, 1998). Although STDP is considered to be a critical mechanism of learning and memory, how STDP can specifically modulate neural connections to form a various type of memory still remains unclear. Here we suggest that the profiles of STDP can determine the types of memory in learning – short-term or long-term. We propose an idea that short-term and long-term memories can originate from two distinct STDP rules: Asymmetric STDP (AS) (Gütig et al, 2003) and Symmetric STDP (SS). The main difference between AS and

SS is the symmetry of weight dependent learning rate profile: In the AS model, weak synapses are easily strengthened but hard to be weakened, while SS model makes both weak and strong synapses harder to change their synaptic weights compared to mid-range strength synapses.
To test our idea, we constructed a model feedforward neural network, consisting of two layers of leaky integrate-and-fire neurons; then we introduced random patterns of spike train to the networks as a simulation of information received. We defined memory as the ability of a system to retrieve consistent responses when trained pattern of spikes is introduced to the system repeatedly. Based on this definition, we confirmed that both AS and SS systems were capable of forming memories. However, the two systems showed noticeable differences in terms of memory sustainability and appendability: Networks with AS created memories that decayed relatively fast and was easily replaced by new information appended, while networks with SS formed memories that did not show any noticeable decay and persisted even when new information was added. Such characteristics of AS and SS networks appeared similar to the feature of short-term and long-term memories, respectively. Lastly, we tested a new learning rule, hybrid STDP, which is made from the linear combination of AS and SS kernels. Our simulation of hybrid STDP could generate memories with intermediate properties between short-term and long-term memories.
Overall, our result indicates that a small difference in synaptic learning rule may cause a significant difference in the performance of a memory system. Our study implies that the nature of short-term and long-term memory might not be completely different but share the same mechanism of memory formation with different learning rules.

Title: CD44 adhesion molecule involved in molecular mechanisms responsible for stabilization of dendritic spines

Authors: ***A. SKUPIEN**[1], M. ROSZKOWSKA[2], G. WILCZYNSKI[1], J. DZWONEK[1]; [1]Neurophysiol., Nencki Inst. of Exptl. Biol. Polish Ac, Warszawa, Poland; [2]Lab. of Cell Biophysics, Nencki Inst. of Exptl. Biol. Polish Acad. of Sci., Warsaw, Poland

Abstract: Dendritic spines are neuronal protrusions, each of which receives input typically from one excitatory synapse. Morphological changes in these actin-rich structures are associated with learning and memory formation. The loss or malformation of spines is also linked to many neurological diseases, which indicates the importance of proper regulation of spine morphology. Remodeling of actin cytoskeleton, the main structural component within dendritic spines, through actin binding proteins (e.g. cofilin), plays a key role in regulating spine structure and stability. It is also known that extracellular matrix (ECM) can regulate the process of synaptic plasticity. CD44 adhesion molecule is a receptor for hyaluronan, main extracellular matrix component in the brain. By its C-terminal domain, CD44 can interact with many intracellular proteins, including those engaged in actin cytoskeleton reorganization. In this study we report that CD44 adhesion molecule influences on dendritic spine morphology and modulates signaling pathways which control cofilin activation. Taking into consideration our pilot studies we hypothesize that CD44 adhesion molecule, focal adhesion kinase (FAK), LIM kinase and cofilin, belong to the same signaling module, which is responsible for regulation of dendritic spine stability.

Abstract: Synaptic cell adhesion molecules regulate signal transduction, synaptic function, and plasticity. However, their role in neuronal interactions with the extracellular matrix (ECM) is still not well understood. Here, we report that the CD44, a transmembrane receptor for hyaluronan, modulates synaptic plasticity. The diminished expression of CD44 affected the synaptic excitatory transmission of primary hippocampal neurons, simultaneously modifying dendritic spine shape. The frequency of miniature excitatory postsynaptic currents decreased, accompanied by dendritic spine elongation and thinning. These structural and functional alterations went along with a decrease in the number of presynaptic Bassoon puncta, together with a reduction of PSD95 levels at dendritic spines, suggesting a reduced number of functional synapses. Lack of CD44 also abrogated spine head enlargement upon neuronal stimulation. Moreover, our results indicate that CD44 contributes to proper dendritic spine shape and function by modulating the activity of actin cytoskeleton regulators i.e. three small Rho GTPases (RhoA, Rac1, and Cdc42). Thus, CD44 appears to be a novel molecular player that is involved in the regulation of functional and structural plasticity of dendritic spines.

Title: Dendritic spine changes associated with long-term synaptic plasticity in nigral dopamine neurons.

Authors: *M. KIM, M. PARK;
Sungkyunkwan Univ. Sch. of Med., Suwon-Si / Gyeonggi-Do, Korea, Republic of

Abstract: Glutamatergic synapses in midbrain dopamine neurons play a critical role in reinforcement learning and drug addictions. Very recently, we have reported that dopamine neurons in the substantia nigra pars compacta (SNc) have two morphologically and functionally distinct types of glutamatergic synapses on the same dendrite; spine synapses and shaft synapses. However, it is not clear whether the dendritic spines in dopamine neurons like other neurons

undergo synaptic plasticity. Therefore, we have explored whether the dendritic spines are synaptically plastic or not in nigral dopamine neurons, using high-resolution two-photon confocal microscopy and wholl-cell patch-clamp recordings in the TH-eGFP mouse midbrain slices. By consecutive focal glutamate uncaging pulses on the tip of spine heads or dendritic shafts, similar to physiological release of neurotransmitter glutamate, we found that glutamate stimulation above a certain level increased diameter of spine heads and excitatory postsynaptic potentials (EPSPs), that were maintained up to 40 minutes, suggesting the long-term potentiation (LTP). A NMDA receptor antagonist, CPP, blocked these spine enlargements, no significant spine growth occurred. Therefore, we demonstrate that these newly found dendritic spines in nigral dopamine neurons are also plastic and play important role in reinforcement learning and drug addictions in midbrain dopamine neurons.

Title: Localization and regulation of nogo receptor 1 and its partners.

Authors: *A. T. BRODIN, K. WELLFELT, G. SMEDFORS, E. ARVIDSSON, L. OLSON, T. E. KARLSSON;
Neurosci., Karolinska Institutet, Solna, Sweden

Abstract: Nogo receptor 1 (NgR1) together with multiple partners regulates neurite growth. It has been shown that NgR1 restricts plasticity during both development and adulthood. Neuronal activity downregulates NgR1, and the inability to downregulate NgR1 impairs long term memory. Further, overexpression of NgR1 differentially affects spine populations and dendritic structure, as well as response to cocaine sensitization in different brain regions. However, it is yet unknown whether NgR1 acts presynaptically, postsynaptically, or at both sites. Also, while it has been shown that NgR1 is downregulated by activity, there is much unknown about how other components of the NgR1 signalling system are affected, and over what timescale. Therefore we investigate the localization and regulation of NgR1 and its partners. By imaging primary hippocampal cultures containing tagged Nogo-system proteins using confocal and STED microscopy we will characterize the localization of NgR1 and its interacting molecules. We use in situ hybridization to chart the expression of Nogo-related proteins during development. To uncover the regulation of NgR1, we use in situ hybridization to characterize the expression profiles following kainic acid treatment. We will also verify our findings in vitro by charting the regulation of NgR1 and associated proteins in primary hippocampal cultures after pharmacological stimulation. Our results should contribute to the understanding of localization and regulation of Nogo signaling system components.

Title: Structural plasticity of dendritic spines during long-term synaptic depression

Authors: *A. THOMAZEAU[1], M. BOSCH[2], S. ESSAYAN-PEREZ[1], M. F. BEAR[1];

Abstract: Structural modifications of dendritic spines are crucial processes mediating synaptic plasticity, and thus are considered possible structural correlates of learning and memory. The mechanisms underlying structural plasticity of dendritic spines during long-term depression (LTD) are poorly understood. It is also unclear whether those mechanisms are altered in some neurodevelopmental disorders such as Fragile X syndrome, the primary cause of genetically-based mental retardation. By using time-lapse two-photon fluorescence imaging combined with

electrophysiology, we visualized CA1 hippocampal dendritic spines to (1) determine the structural changes they undergo after induction of different forms of LTD, (2) investigate whether this structural plasticity is altered in a mouse model of Fragile X syndrome. We found that NMDAR-dependent LTD, but not mGluR-dependent LTD, is accompanied by a shrinkage of dendritic spines in control mice. We also found that this structural modification is dependent on *de novo* protein synthesis. In contrast, we found that in Fmr1 KO mice, even though the structural changes associated with LTD are intact, the spine shrinkage associated with NMDAR-dependent LTD is no longer dependent on *de novo* protein synthesis. These results further substantiate the importance of dendritic spine dynamic in the expression of LTD, which is known to be altered in Fmr1 KO mice. Therefore they could also be critically linked to the phenotypes of Fragile X syndrome.

Title: Intracerebroventricular administration of growth hormone induces neural morphological changes in the CA1 region of the dorsal hippocampus and the prefrontal cerebral cortex of adult rats

Authors: J. OLIVARES HERNANDEZ[1], *F. A. GARCÍA-GARCÍA[2], E. JUAREZ AGUILAR[1];
[1]Biomedicina, [2]Univ. Veracruzana, Xalapa, Mexico

Abstract: Growth hormone (GH) has different positive effects on the brain function. For example, GH administration improves learning and memory, regulates neurogenesis, myelin synthesis and axonal regeneration. In addition, GH also enhances expression of the AMPA and NMDA receptors that are associated with synaptic plasticity. Currently, there are no studies that examining the trophic effect of GH on neurons structure. Therefore, the aim of the present work was to examine the effect of the intracerebroventricular (I.C.V.) injection of GH on dendritic morphology in the pyramidal neurons of the CA1 region of the dorsal hippocampus and Layer III of prefrontal cortex (PFC) using Golgi-Cox stain method and its subsequent analysis by the Sholl

method. Adult male Wistar rats received a daily ICV injection of GH (120 ng) per seven days, being euthanized 21 days later. Our data shows that GH administration increased the total dendritic length in pyramidal neurons of CA1 region of the dorsal hippocampus ($p<0.001$), compared with control rats that did not receive the GH injection. In the same way, GH induced a significant increment in the total dendritic length in pyramidal neurons of the Layer III of the PFC ($p = 0.013$). Interestingly, the branch-order analysis also revealed an increase in the dendritic length of pyramidal neurons of the hippocampal CA1 region specifically from third to eighth orders in GH treated animals ($p < 0.001$), compared with neurons from control rats. The same effect was observed in Layer III of the PFC but only in the range of the third to sixth order ($p < 0.001$). Altogether, our results suggest the participation of GH in the synaptic plasticity through the regulation of the dendritic tree density.

Title: Analysis of the specificity of MMP-9 inhibitor on the nectin-3 shedding upon neuronal stimulation

Authors: *E. REJMAK-KOZICKA, M. DZIEMBOWSKA, K. KALITA, L. KACZMAREK; Nencki Inst. of Exptl. Biol., Warsaw, Poland

Abstract: Structural changes of dendritic spines occurring in response to synaptic activity are accompanied by changes in the connections between pre- and postsynaptic membrane. The strengthening and weakening of these contacts can be modulated by nectin-3 that is postsynaptic Cell Adhesion Molecule (CAM), which role to interact with presynaptic nectin-1 is well known. Previously we described that the increased nectin-3 proteolysis under chronic stress conditions correlates with the elevated MMP-9 activity in the rat hippocampal CA1 fragment. The nectin-3 proteolysis was also observed in other model of the strong excitation induced by the seizures triggered by kainic acid. Proteolytic cleavage of the nectin-3 results in the appearance of a 20 kDa nectin-3 derived fragment. The cleavage was inhibited by the MMP-9 inhibitor (inhibitor I). To test the connection between the nectin-3 shedding and activity of the MMP-9 *in vitro* we

performed experiments on the hippocampal cultures. The results also shown that this process depends on the activation of NMDA receptor and the presence of Ca^{2+} / calmodulin. Moreover, taking into account the possibility of non-specific activity of the applied inhibitor we experimentally demonstrated its specific activity towards MMP-9 by conjugating inhibitor I with biotin with following purification on the magnetic streptavidin beads. We analyzed the binding capacity of inhibitor I to the endogenous and exogenous MMP-9 by gel zymography. Due to the MMP-9 low brain expression level and its secretion on the synapse upon neuronal stimulation we decided to use the hippocampi from rats injected with kainic acid (10h after injection, 10 mg/kg) for our experiments. The activity of MMP-9 in the inhibitor-bound probe was detected. The inhibitor's specificity towards MMP-9 was supported by the absence of MMP-2 activity in this probe, which is another abundant in the brain metalloproteinase showing gelatynase activity. This results strongly confirm that inhibitor I is specific towards MMP-9 and this protease causes fragmentation of the nectin-3.

Title: Exploring the molecular mechanisms underlying rapid estrogenic modulation of cortical connectivity

Authors: *P. RAVAL[1], K. J. SELLERS[1], J. MUKHERJEE[2], N. J. BRANDON[2,3], D. P. SRIVASTAVA[1];
[1]Basic and Clin. Neurosci., King's Col. London, London, United Kingdom; [2]AstraZeneca-Tufts Lab. for Basic and Translational Neurosci., Tufts Univ. Med. Sch., Boston, MA; [3]AstraZeneca Neurosci. IMED, Cambridge, MA

Abstract: There is increasing evidence that the regulation of structure and function of neuronal circuits is an essential component of normal cognitive function and behaviour. Several studies

have demonstrated concurrent changes in connectivity between neurons during and following the acquisition of learned behaviours. Estrogens, particularly its biologically active form 17β-estradiol (E2), have repeatedly been illustrated to have powerful influences over cognitive function and behaviour, which is believed to be, in part, driven by estrogenic regulation of neuronal connectivity. Specifically, estrogens have consistently been illustrated to regulate dendritic spine dynamics and shape synapse structure and function. It is becoming clear that estrogens have two modes of actions: classically, they activate and translocate the 'nuclear' estrogen receptors (ER), alpha (ERα) and beta (ERβ), to the nucleus and exert effects on neuronal circuitry via gene transcription, which manifest over hours to days. Alternatively, estrogens can also act rapidly through non-genomic actions via intracellular signalling within minutes to hours. These rapid effects can result in the initiation of signalling pathways leading to a number of cellular events, many of which are independent of gene transcription such as: dendritic spine turnover/remodelling; protein/receptor trafficking; and local protein translation. However, the molecular and cellular mechanisms that underlie, and the ER(s) responsible for this rapid regulation of cognition, have yet to be fully elucidated.
As the remodelling of cortical connectivity is believed to be an essential component of cognitive function, we have focused on understanding how estrogens can regulate specific cellular events such as, spine remodelling and how target protein and receptor trafficking/expression and local protein translation contribute to this in primary cortical neurons. Employing a combination of confocal, super-resolution and live imaging, we have monitored dendritic spine turnover in response to acute E2 treatment and found that there is a transient increase within 30 min. Additionally, through imaging and biochemical assays such as, Fluorescent Canonical Amino acid Tagging (FUNCAT) and Surface Sensing of Translation (SUnSET) we have found that there is a biphasic increase of local protein translation interestingly mirroring the activation of specific pathways such as ERK1/2 and mTOR and an increase in PSD-95 expression levels. These data provide an insight into the signalling pathways and cellular events that potentially contribute to the effects of estrogen on dendritic spine plasticity.

Title: Early postnatal manganese exposure affects primary motor cortex development in adolescent mice

Authors: *C. E. MOYER[1], S. A. BEAUDIN[2], D. R. SMITH[2], Y. ZUO[1];
[1]Dept. of Molecular, Cell, and Developmental Biol., [2]Dept. of Microbiology and Envrn. Toxicology, Univ. of California Santa Cruz, Santa Cruz, CA

Abstract: Developmental manganese exposure is associated with fine motor deficits in children, as well as in animal exposure models. The impaired fine motor control that develops in response to developmental manganese exposure is thought to result from nigrostriatal dopamine hypofunction and receptor disturbances in young and adult animals. However, it is not known whether developmental manganese exposure also impairs the structure and function of the primary motor cortex (M1). M1 plays an important role in fine motor control, and plasticity of excitatory synapses in M1 is associated with skilled motor learning in animals. Thus, the objective of the current study was to determine if developmental manganese exposure disrupts excitatory synapse plasticity in M1 of adolescent mice. Mice were orally exposed to manganese daily prior to weaning. Taking advantage of the sparse labeling of cortical layer V pyramidal neurons in *Thy1*-YFP-H line mice, and using *in vivo* two-photon microscopy, we longitudinally followed dendritic spines (yellow fluorescent protein (YFP)-labeled postsynaptic structures of presumptive excitatory synapses) on the apical dendrites of M1 layer V pyramidal neurons of adolescent mice (approximately one month old). Alterations of dendritic spines in M1 were observed during adolescence in mice that had been exposed to manganese prior to weaning relative to littermate controls. These findings suggest that early postnatal manganese exposure affects adolescent cortical excitatory synapse development in M1, and may impair M1 circuitry. Further studies are required to determine if the effects of early manganese exposure on synapse plasticity in M1 contribute directly to the fine motor dysfunction reported in animal models of developmental manganese exposure.

Abstract: Dendritic spines are critical for learning and memory. It has been shown that the dynamic change of spines underlied higher cognitive functions. However, the mechanism governing such spine development is unclear yet. This study thus focused the mechanism of physical exercise on spines plasticity. We used two-photon microscopy to find that continuous forced exercise in mice could prevent the loss of spines in barrel cortex, and improve animal working memories in novel texture discrimination task. The exercise could also elevate the expression of BDNF in barrel cortex. Moreover, the application of TrkB inhibitor suppressed such beneficial effects of exercise on spine dynamics. In conclusion, we proposed that physical exercise modulates spine plasticity in barrel cortex via TrkB-BDNF pathway. This study provides new insights for intervention of neurodegenerative disease and mental illnesses.

Title: Age-dependent alterations in dendritic spine dynamics in the somatosensory cortex following whisker stimulation

Authors: *R. L. VOGLEWEDE[1], A. R. DEWITT[1], E. H. TRIMMER[2], R. MOSTANY[1,2]; [1]Neurosci., [2]Pharmacol., Tulane Univ. Sch. of Med., New Orleans, LA

Abstract: Within the brain, stability and plasticity of synaptic connectivity are cooperative forces that operate in tandem during learning and memory processes. Previous research suggests that aged mice display an increased dendritic spine density coupled with an elevated spine turnover ratio within the Layer V pyramidal neurons of the primary somatosensory cortex when compared to young adult mice, indicating that although there may be a higher number of synaptic connections in this brain area of animals age, those synapses also appear to be less stable over time. Functional implications of this elevated turnover with regards to learning and plasticity has not been uncovered. The question remains: is this increase in turnover ratio a compensatory or a maladaptive mechanism that aged animals employ as they learn and form memories associated with sensory experience? To answer this question, in this study we explore the implications of less stable, hyperdynamic synaptic connections within the aged cortex on learning and memory as animals undergo a sensory experience.
To investigate this, we employed sensory manipulation via continuous whisker stimulation with a piezoelectric actuator at 8Hz for 10 minutes a day (a model shown to induce long-term potentiation) over 4 days. We performed chronic *in vivo* two photon imaging through a 4 mm cranial window of apical tuft dendrites of layer V pyramidal neurons within the primary somatosensory cortex of Thy1-eGFP-M male mice within two age sets: young adult (aged 3-5 months) and aged (18-22 months). Mice were imaged over 46 days spanning before, throughout, and following sessions of bundled whisker stimulation. Stimulation occurred from days 8 – 11. Imaging sessions occurred every 4 days (days 0 - 20, 38 - 46) to observe long-term changes in spine dynamics. Additional sessions were held every 24 hours during the peri-stimulation period

(days 6 - 16) to examine these changes with better temporal resolution.
Our results indicate no changes in dendritic spine density as a result of the whisker stimulation protocol in both age groups. However, we observe a significant, acute increase in the dendritic spine turnover ratio at both 4 day and 24 hour intervals following whisker stimulation in the young adult but not aged mice, suggesting that sensory experience-dependent formation and elimination of synapses is impaired in the latter group and an alternative mechanism for sensory learning and memory may be present within synapses as animals reach old age.

Title: Parvalbumin-positive interneurons of the hippocampus show input-dependent structural plasticity

Authors: A. FOGGETTI[1], T. SCHIFFELHOLZ[1,2], *P. WULFF[1];
[1]Inst. of Physiology, Univ. of Kiel, Kiel, Germany; [2]Dept. of Psychiatry and Psychotherapy, Univ. of Kiel, Kiel, Germany

Abstract: Dendritic spines compartmentalize electrical and molecular signaling and on principal cells are recognized as fundamental components for both synaptic transmission and synaptic plasticity. Little is known about spines on inhibitory interneurons. We show that parvalbumin-positive GABAergic interneurons in the mouse hippocampus carry considerable densities of dendritic spines, which undergo input-dependent spatial re-organization in response to behavioural experience.

Abstract: In the mammalian forebrain, the majority of excitatory synapses form on dendritic spines. Changes in the number of dendritic spines are important for brain development, plasticity and the refinement of neural circuits. Psd-95, an abundant scaffolding protein in the postsynaptic density of excitatory synapses, interacts with various signalling and structural molecules tethering them into the postsynaptic density; here, it can play a central role in the processes surrounding both synaptic plasticity and maturity. Evidence from multiple studies have demonstrated that the changes in the structure and function of neuronal circuitry occurs during acquisition of learned behaviours. Multiple studies have shown that 17β-estradiol (E2), the major biologically active form can modulate cognition within a rapid time frame through changes in neuronal circuitry and regulation of dendritic spines. Furthermore, it is clear that concurrent with the action of E2 on modulation of dendritic spine numbers it is also able to recruit PSD-95 to these novel dendritic spines. While these effects have been attributed in the main to signalling via the estrogen receptors (ER) ERα and ERβ, recent studies have suggested that the newly identified E2 sensitive receptor, G-protein coupled estrogen receptor 1 (GPER1), may also mediate E2-dependent modulation of cognition. However, how cognition is modulated through GPER1 and what signalling pathways or cellular events are initiated is not clear.

There is an increasing body of evidence that suggests that GPER1 may induce dendritic spine plasticity in a rapid time frame. We have focused on elucidating the molecular mechanisms involved in the downstream regulation of this rapid dendritic spine remodelling in response to GPER1. Here we report using super resolution microscopy that GPER1 is present at a subset of synapses in excitatory cortical neurons where it forms nanodomains colocalising with PSD-95 in the postsynaptic density. We demonstrate that precise pharmacological activation of GPER1 leads to a rapid linear increase in dendritic spines which is dependent on the activation of specific signalling cascades. Concurrent with this we have monitored the spatiotemporal dynamics of synaptic proteins including Psd-95 in response to activation of GPER1. Additionally through biochemical assays we have found that this interaction between Psd-95 and GPER1 is vital for GPER1 to exert its responses in the refinement of neuronal circuitry. These data demonstrate that in cortical neurons, E2 signalling via GPER1, is capable of remodelling neuronal circuits by increasing the number of excitatory synapses.

Title: Actin dynamics contribute to the storage of drug-associated memories in both sexes.

Authors: *E. J. YOUNG[1], G. RUMBAUGH[2], C. A. MILLER[1];
[1]Metabolism & Aging, Neurosci., [2]Neurosci., Scripps Res. Inst., Jupiter, FL

Abstract: Encountering drug-related environmental cues, even after long periods of abstinence, can trigger retrieval of deeply engrained associative memories capable of eliciting drug seeking behavior. Dendritic spines are thought to serve as a structural storage site for memories, with actin polymerization serving a critical role in encoding the memory. We have previously reported the unexpected finding that inhibiting direct actin depolymerization within the AMY results in the immediate and persistent disruption of methamphetamine (METH)-associated memories, independent of retrieval, with a concomitant reversal of AMY dendritic spine density to baseline levels. However, the same manipulation has no impact on fear or food reward

memories, which also rely on the AMY. These findings indicate that METH-associated memories are supported by actin dynamics that remain uniquely active long after consolidation, allowing for their selective, retrieval-independent disruption. Unfortunately, the therapeutic potential of a direct actin depolymerizer is limited because of the number of peripheral processes that critically depend on actin. In previous work, we found that nonmuscle myosin II (NMII) triggers spine actin polymerization by exerting mechanical force on actin filaments and more recently, we demonstrated that NMII can be safely administered systemically to disrupt drug seeking behavior in the same way that direct actin depolymerization does. Thus, NMII represents an attractive target for pharmacotherapeutic development to prevent relapse. However, an abundance of evidence indicates that sex differences exist in drug abuse, so any potential therapeutic should also be thoroughly investigated in females. Therefore, we determined the impact of NMII inhibition on memory maintenance and drug seeking behavior in females. Similar to what we observed with males, inhibiting NMII in the basolateral amygdala complex (BLC) prior to context-induced reinstatement of self-administration disrupted drug seeking behavior. This single treatment produced a persistent disruption of drug seeking behavior, lasting at least one month. The therapeutic potential of NMII inhibition in females was extended by successful disruption of a METH-associated memory (conditioned place preference), but not fear memory, following systemic NMII inhibition. The METH-associated memory loss was accompanied by a marked decrease in BLC spine density. While spine density and the corresponding memory was unchanged in fear memory animals following NMII inhibition. Together, this data further argues for the development of a small molecule inhibitor of NMII for the prevention of relapse.

Abstract: Alterations in dendritic spine numbers are linked to deficits in learning and memory. While we previously demonstrated that postsynaptic plasticity-related gene 1 (PRG-1) controls lysophosphatidic acid (LPA) signaling at glutamatergic synapses via presynaptic LPA-receptors, we now show that PRG-1 also affects spine density and synaptic plasticity in a cell-autonomous fashion via protein phosphatase 2A (PP2A)/ITGB1 activation. PRG-1-deficiency reduces spine numbers and ITGB1 activation, alters long-term potentiation (LTP), and impairs spatial memory. The intracellular PRG-1 C-terminus interacts in a LPA-dependent fashion with PP2A, thus modulating its phosphatase activity at the PSD. This results in recruitment of adhesome components src, paxillin and talin to lipid rafts and ultimately in activation of ITGB1. Consistent with these findings, activation of PP2A with FTY720 rescues defects in spine density and LTP of PRG-1-deficient animals. These results disclose a mechanism by which bioactive lipid signaling via PRG-1 could affect synaptic plasticity and memory formation.

Title: Dendritic coordination between excitatory and inhibitory plasticity

Authors: C. WIERENGA[1], D. KRUIJSSEN[1], *H. HU[1], B. RÓSZA[2];
[1]Univ. of Utrecht, Utrecht, Netherlands; [2]Two photon Imaging Lab. / Inst. of Exptl. Med. of the Hungarian Acad. of Sci., Budapest, Hungary

Abstract: For proper functioning of neuronal circuits during development and learning, changes in excitatory and inhibitory synapses need to be coordinated. Here we ask if excitatory and inhibitory plasticity is coordinated between nearby synapses within dendrites of CA1 pyramidal neurons.
We applied two-photon laser scanning microscopy to identify axo-dendritic crossings between dendrites of CA1 pyramidal cells and GABAergic axons in organotypic cultures of GAD65-GFP mice. Using two-photon glutamate uncaging, we activated several dendritic spines within ~10 μm of such crossings while the postsynaptic neuron was depolarized through a patch pipette to allow potentiation of the stimulated spines. We tracked possible morphological changes on the inhibitory axon at the crossing in response to the stimulation of nearby spines.
At 36% (12/33) of stimulated crossings, we observed a response of the GABAergic axon to the activation of nearby spines. In 42% of responding axons we observed a new inhibitory bouton appearing at the axo-dendritic crossing, while in the other cases the pre-existing inhibitory bouton at the crossing increased significantly in size and intensity. The induced inhibitory changes persisted for up to 40 minutes after the stimulation protocol. Without stimulation, axon intensity did not change during the imaging period (80 mins). Uncaging glutamate directly around a GABAergic axon did not induce bouton growth, indicating that the postsynaptic dendrite played an essential role in stimulating inhibitory bouton growth. We are currently analyzing how inhibitory changes are correlated with volume changes in stimulated spines.
Our results suggest that local mechanisms exist that monitor and regulate the local excitation-inhibition ratio within dendrites.

Title: Dissection of molecular mechanism of *Aplysia* Sec7 protein-induced neurite outgrowth.

Authors: Y.-W. JUN[1], J.-A. LEE[3], B.-K. KAANG[4], *D.-J. JANG[2];
[1]Kyungpook Natl. Univ., Snagju-si, Korea, Republic of; [2]Kyungpook Natl. Univ., Sangju-si/gyeongsangbuk-Do, Korea, Republic of; [3]Hannam Univ., Daejeon, Korea, Republic of; [4]Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: ADP-ribosylation factors (ARFs) are small guanosine triphosphatases of the Ras superfamily involved in membrane trafficking and regulation of the actin cytoskeleton. *Aplysia* Sec7 protein (ApSec7), a guanine nucleotide exchange factor for ARF1 and ARF6, induces neurite outgrowth and plays a key role in 5-hydroxyltryptamine-induced neurite growth and synaptic facilitation in *Aplysia* sensory-motor synapses. However, molecular mechanism of ApSec7 functions was not clear. In the present study, firstly, we found that the coiled-coil domain of ApSec7 plays dual roles in intracellular targeting: efficient plasma membrane targeting through homodimer formation, and nuclear exclusion through either a CRM1-dependent or -independent pathway. Secondly, we found that ApSec7 could bind to active ARF6 and PI(3,4,5)P_3 and is localized to the plasma membrane, while another isoform, ApSec7(VPKIS) could bind to active ARF1 and PI4P and is localized to the Golgi complex. Thirdly, the activation of *Aplysia* ARF6 (ApARF6) as a downstream signaling of ApSec7 could induce neurite outgrowth in *Aplysia* sensory neurons. ApARF6-induced neurite outgrowth was inhibited by the co-expression of a Sec7 activity-deficient mutant of ApSec7 (ApSec7-E159K) via sequestration of active ApARF6 through the binding of the pleckstrin homology domain of ApSec7 at the plasma membrane. Thus, the results of the present study suggest that ARF6 signaling may be involved in downstream signaling of ApSec7-induced neurite outgrowth in *Aplysia* neurons.

Institute, Saitama Univ., Saitama, Japan; [5]Sch. of Life Science, South China Normal Univ., Guangzhou, China

Abstract: We previously found that in the initial phase of LTP, cofilin is transported to the spine, forms a stable complex with F-actin, persistently accumulates at the spine, and consolidates spine expansion. To spatiotemporally regulate cofilin activity during LTP, we introduced CALI (chromophore-assisted light inactivation) system, a technique to inactivate target proteins with light irradiation through reactive oxygen. For this purpose, we generated a fusion protein between cofilin and SuperNova (SN), a protein of GFP family that generates reactive oxygen upon light illumination. To validate this system, a persistent enlargement of the spine (structural LTP) was induced with two-photon (2P) uncaging of MNI-glutamate in the single dendritic spine in the hippocampal slice culture, which express SN-fused cofilin (CFL-SN), and 559 nm laser was subsequently irradiated. Followed by laser irradiation on the single spine 10 min after LTP induction, the spine volume gradually decreased. Decrease in the spine volume was also observed when laser was irradiated 20, 30 and 40min respectively after LTP induction. However decrease in the spine volume was no longer observed when laser was irradiated 50 min after LTP induction. Furthermore, the laser irradiation on the spine 1 min before sLTP had no effect on the spine enlargement. The laser irradiation on the spine without LTP induction had no effect on the spine volume. These results indicate cofilin is critical for maintenance of LTP up to 40 min after induction, and the inactivation of cofilin had negligible effect on LTP induction and the volume of unstimulated spine . To test system in memory formation, we expressed CFL-SN in hippocampal neurons by injecting AAV-floxed-CFL-SN

into CA1 region of CaMKII-Cre mouse, then implanted an optical fiber above the virus injection region. Memory was examined by Inhibitory Avoidance (IA) task. Memory was not impaired just by overexpress of CFL-SN in CA1 neuron. In contrast, memory was significantly impaired when 593 nm was irradiated on CA1 neurons expressing CFL-SN 2 min after an electrical shock at day 1. On the other hand, memory was not impaired when 593 nm was irradiated 1 min before the electrical shock. These data are consistent with those from slice culture. This new method can specifically erase memory shortly (2 min) after memory formation without any effect on subsequent induction of memory.

Title: The formation concept of protected areas of the human neocortex in focal damage

Authors: ***V. AKULININ**, A. MYTSIK, S. STEPANOV, V. RASUMOVSKY;
Omsk State Med. Univ., Omsk, Russian Federation

Abstract: The study of neocortex compensatory and remedial changes in acute and chronic ischemia is an actual objective of neuromorphology. In this research, using histological, immunohistochemical neurons (NSE, Calbindin D28k, NPY), synapses (p38) and glial cells (GFAP) verification methods in morphometrical analysis, the focal neocortex changes were investigated in patients, who had a surgery for traumatic brain injury (n=5, biopsy) and brain tumor (n=25, biopsy). The patient's neocortex after clinical death (n=7, autopsy) was studied as well. 10 patients, died from accidental causes and served as controls. Morphometric image analysis of 25 fields of view for each case was performed using ImageJ 1.48, determines the area (μm^2) of fluorescent granule marker and number cells in sight. Statistical hypothesis testing was carried out used the program STATISTICA 8.0 with a nonparametric (ANOVA Friedman, Mann-Whitney, Wilcoxon, χ^2, frequency table, cluster analysis and multidimensional scaling) criteria. It is established that in different types of ischemia, comparing with the control, there were statistically significant differences between randomly selected neocortex fields of view in almost all the variables studied (total numerical density of neurons and astrocytes, immunopositive granules square, granules numerical density, the relative content of reactively changed neurons). In the control group the differences were observed mainly between the layers

(vertical stratification) of neocortex, while in ischemia these differences were between neighboring areas of every layer as well (vertical and horizontal changes stratification). The focuses of destructively changed neurons dominance around the fields of undamaged neurons were defined. The latter was manifested most clearly in chronic ischemia (tumors, postreanimation period). In comparison with the control, the following features were typical for these areas: 1) moderate deficiency of the total neurons numerical density (10-25%), 2) the dominance of normochromic neurons (50-70% of all neurons), 3) the high concentration of NSE-, Calbindin-positive neurons (110-140% of control group), 4) the increased content of NPY-positive material (120-200% of control group), 5) the proliferation of gliocytes and increased content of GFAP-positive material (120-140% of control group). We suggest that in chronic ischemia there are areas existing and forming around small focuses of destruction of the neocortex, that are protected from excite-toxic mechanisms of secondary ischemic damage.

Title: Enhancement of neuronal differentiation of mice olfactory epithelium stem cells by DNA methylation inhibition

Authors: *I. B. FRANCO ESTRADA[1], G. R. R. RAMIREZ-RODRIGUEZ[2], M. L. G. LAMAS GREGORI[3];
[1]Ctr. of Res. and Advanced Studies of the Nat, Ciudad DE Mexico, Mexico; [2]Lab. of neurogenesis, Natl. Inst. of Psychiatry Ramón de la Fuente Muñiz, México., Mexico City, Mexico; [3]Pharmacobiology, Ctr. of Res. and Advanced Studies, Mexico City, Mexico

Abstract: The olfactory epithelium is considered as a source of progenitors and stem cells with a high proliferation rate and neural differentiation capacity. Due to these features, olfactory epithelium cells (OECs) have been considered as possible tools for regenerative stem cell therapies in neurodegenerative diseases like Parkinson and Alzheimer. OECs differentiation

potential is acquired in response to intrinsic and extrinsic signals, which produce, among other effects, changes in DNA methylation and chromatin modifications. However, these mechanisms in mice OECs (mOECS) are not fully understood and the role of DNA methylation during their neuronal differentiation is still unknown. The aim of the present study was the *in vitro* characterization of mOECs so as to analyze their DNA methylation profile in order to evaluate the hypothesis that DNA methylation inhibition could improve their neuronal differentiation efficiency. The olfactory epithelium was isolated from five weeks old male Swiss Webster mice and cultured in DMEM-F12+10%SFB. On passages P2-P10 we analyzed qualitatively DNA methylation and demethylation-related genes (Dnmt1, Dnmt3a, Dnmt3b, Gadd45a and Gad45b) by RT-PCR and we show that mOECs maintain the expression of DNA methyltransferases in all the passages analyzed. Also we determined the DNA methylation (5mC and MeCP2) and hydroximethylation (5hmC) profiles by immunofluorescence. In order to induce neuronal differentiation, mOECs were exposed to retinoic acid and forskolin for 7 days. In these cultures we analyzed the morphology and expression of mature neuronal-associated genes (MAP2, NSE) by immunofluorescence. NSE was expressed in 69.5% on differentiated mOECs, whereas 35% were immunopositive to MAP2. We evaluated the effect of the pretreatment of mOECs with a specific DNMT1 inhibitor (Procainamide) before neuronal induction. Our results show increased levels of MAP2 mRNA expression in olfactory epithelium cells treated with 1.0mM of procainamide compared to the control. These results suggest that DNA methylation plays an important role during OECs differentiation and it may support their application for stem cell therapy.

Title: Spines in parvalbumin-expressing interneurons undergo structural reorganization depending on behavioral experience

Authors: *D. KAUFHOLD, M. STRÜBER, M. BARTOS;
Systemic and Cell. Neurophysiol., Inst. of Physiol., Freiburg, Germany

Abstract: Dendritic spines provide electrical and biochemical compartments and are thus critical sites of synaptic transmission, synaptic plasticity as well as structural modifications of neuronal micro-circuits. In principal cells structural changes of dendritic spines correlate with long-term changes of synaptic input strength and memory formation. In contrast, GABAergic cells including perisoma-inhibiting parvalbumin-positive interneurons (PVIs) have been considered non-spiny. Recent studies showed behavior-dependent changes in protein expression levels in PVIs, structural remodeling of PVI axonal fibers and functional plasticity at their excitatory input synapses suggesting that DG PVIs may undergo structural and functional changes at their dendritic compartments. To address this open question we stereotactically injected an adeno-associated virus carrying the GFP reading frame inverted in a flip-excision cassette (AAV-FLEX-GFP) into the dentate gyrus (DG) of PV-Cre mice with subsequent detailed morphological analysis. We identified dendritic spines particularly in rodent DG PVIs. Here we asked whether PVI spines receive functional synaptic inputs and whether spine density can be altered in dependence on behavior.
We show that (1) hippocampal PVIs are indeed spiny but particularly those residing in the DG and not in CA3 and CA1; (2) about one third of DG PVIs are spiny with a maximal spine density of 0.57 ± 0.031 (SEM) spines/µm dendritic length; (3) PVI spines can be classified in stubby, thin and mushroom spines according to their size and shape; (4) unexpectedly, PVIs with somata at the hilus-granule cell layer border show higher spine densities than PVIs in the granule cell layer or close to the molecular layer; (5) PVI spine densities were higher in the dorsal DG than in the ventral DG. By electron microscopy we show that spine heads receive putative glutamatergic and spine necks GABAergic synaptic inputs. 2-Photon Ca^{2+}-imaging further revealed that these inputs are functional. To examine whether dendritic spines are influenced by behavioral experience, we kept mice under conditions of enriched environment for 3 weeks. We observed a structural change in spines suggesting alterations of synaptic strength and connectivity. Thus, PVI dendritic spines are functional and undergo structural changes upon behavioral experience.

Title: Neural circuit rewiring in the frontal association cortex of social defeated mice

Authors: *T. XU, Y. SHU;
Wuhan Natl. Lab. For Optoelectronics, Hubei, China

Abstract: Chronic stress is associated with occurrence of many mental disorders accompanied by alterations in neural morphology. Growing evidence, derived mostly from studies in medial prefrontal cortex, suggest that prefrontal cortex is involved in the stress response. The dendritic reorganization in pyramidal neurons of the prefrontal cortex has been investigated *in vitro* intensely. However, information for dynamic rewiring in the prefrontal cortex induced by chronic stress is still incomplete due to the lack of study *in vivo*. In this work, we determined the effects of chronic social defeat stress on spine plasticity of the frontal association cortex in *Thy1*-YFP H line transgenic mice *in vivo* by two-photon imaging. Unexpectedly, we found lower spine formation rate but higher survival rate of newly formed spines in the frontal association cortex of defeated animals, which ultimately results in the significant increase of new spine number. These findings demonstrate that chronic stress can lead to the newly persistent spine gains in the frontal association cortex and indicate this kind of adaptive change may relate to a certain memory about stress experience.

Title: PGE1 in liposomes containing antagonized dendritic spine loss and reduction of VEGF & VEGFR2 in hippocampus of diabetic rats

Authors: *M. C. MOSTALLINO[1], F. BIGGIO[2], V. LOCCI[2], L. BOI[2], M. L. MANCA[2], A. M. FADDA[2], G. BROTZU[3], G. BIGGIO[2,1];
[1]Natl. Res. Council, CNR, Monserrato, Italy; [2]Life and Envrn. Sci., Univ. of Cagliari, Cagliari, Italy; [3]BioRicerca, Cagliari, Italy

Abstract: Diabetes mellitus is a common metabolic disorder that can lead to neurological complications such as cognitive impairment and dementia. In recent years, different clinical studies have drawn a clear association between type 1 diabetes with alterations in learning and memory. These clinical findings are strongly supported by data obtained in a rat model of type 1diabetes showing an impairment in learning and memory function. Cognitive impairment seems to be associated with modification of hippocampal synaptic plasticity, neurogenesis, reduced dendritic spine densities and glutamate receptor binding/expression in rat brain and reduced hippocampal and cortical volumes in humans. Diabetes related impairments in cognition and neural circuits function could be the consequence of the progressive damage at vascular level. Prostaglandins are cyclic, oxygenated fatty acids that exert a potent positive action on vascular endothelium in many tissues. Given the prostaglandins undergo to regulation by the rapid action of different enzimes we included PGE1 into liposomes made with phosphatidilcholine and Poly-L-lysine. These liposomes (1μg/kg) were intraperitoneally administered (twice a week for three months) to rats in which diabetes was induced by streptozotocin injection (70 mg/Kg). The glycemia was checked one time a week and 1 UI insulin retard was administered. Control rats and diabetics rats treated with saline has been used as control. Rats were sacrificed after three months. The dendritic spines density and morphology, VEGF (vascular endothelial growth factor) and VEGF-R2 (tyrosine kinase receptor of VEGF) expression levels were evaluated in the hippocampus and frontal cortex. In addiction, morphology by histochemistry and apoptosis were studied in gastrocnemius muscle, lungs and kidneys. All these parameters resulted altered in diabetic rats treated with saline while they were similar to those of control animals in diabetic rats treated with liposomes containing PGE1. The results suggest that such treatment is able to antagonize the neurochemical consequences elicited by experimental. This treatment can be considered an efficaceous terapy to counteract the negative effects of diabete in different vascular districts, brain included.

Title: NMDA receptor signaling mechanisms in activity-dependent spine shrinkage.

Authors: *I. S. STEIN, K. ZITO;
Ctr. for Neurosci., UC Davis, Davis, CA

Abstract: The modification of brain circuits in response to sensory stimuli and heightened synaptic activity is essential for learning and memory. The formation and retraction of dendritic spines contribute to this activity-dependent circuit refinement. Indeed, the pruning of excessive dendritic spines during development has been linked to improvements in behavioral performance. In addition, increased spine shrinkage and loss of dendritic spines, as seen in neurological brain disorders and following brain injury, is associated with cognitive deficits. What are the molecular mechanisms driving shrinkage and elimination of dendritic spines in response to neural activity? Morphological changes of dendritic spines are closely correlated with changes in synaptic strength. Spine shrinkage, like long-term depression of excitatory synaptic transmission (LTD), is driven by low-frequency glutamatergic stimulation and subsequent activation of the NMDA-type glutamate receptor (NMDAR). We have recently shown that NMDAR signaling can drive shrinkage of dendritic spines independent of ion flux through the NMDAR, and that activation of p38 MAPK is required for this non-ionotropic NMDAR-dependent spine shrinkage. Currently, we are using a combination of two-photon imaging and biochemical analysis to further investigate the downstream mechanisms involved in activity-dependent spine shrinkage and synaptic depression. Results from these experiments will lead to a better understanding of the mechanisms that drive the shrinkage and elimination of dendritic spines normally during neuronal circuit refinement and extensively in disease.

Title: The RapGEF Gef26 regulates synaptic development via inhibition of BMP signalling

Authors: *K. HEO;
Seoul Natl. Univ., Seoul, Korea, Republic of

Abstract: Synaptic development and plasticity are critically dependent upon transsynaptic retrograde signaling from postsynaptic cells to presynaptic terminals. At the *Drosophila* neuromuscular junction (NMJ), the BMP homolog Glass bottom boat (Gbb) is secreted from postsynaptic muscles and regulates the growth and function of presynaptic terminals. Here, we present evidence that Gef26, a guanine nucleotide exchange factor for Rap small GTPases, acts together with Rap1 to restrain synaptic growth of NMJs. Mutations in *gef26* cause NMJ overgrowth characterized by excessive satellite bouton formation. This defect is rescued by presynaptic, but not postsynaptic, expression of Gef26. Genetic interactions indicate that Rap1 is a major target for Gef26 in the regulation of synaptic growth, and provide evidence that synaptic overgrowth in *gef26* or *rap1* is caused by elevated BMP signaling. *gef26* and *rap1* NMJs display elevated levels of phosphorylated Mad (p-Mad), a readout of BMP signaling. Synaptic overgrowth in *gef26* and *rap1* is sensitive to the level of BMP signaling. Based on our data, we propose that GEF26/Rap1 signaling regulates synaptic development by inhibiting presynaptic BMP signaling. We are currently investigating the cellular mechanism underlying Gef26/Rap1 regulation of BMP signaling.

Abstract: Neuroplasticity plays an important role in the regulation of brain functions, disruptions of which are associated with mood disorders and cognitive impairment. Neuroplasticity can be altered by neuroactive medications and by aging. Vortioxetine, a multimodal antidepressant, has shown positive effects on cognitive functions in both pre-clinical and clinical studies. In animal studies, vortioxetine was shown to regulate functional plasticity, such as long-term potentiation, and structural plasticity, such as dendritic branching and spine morphology via an increase in glutamate neurotransmission. Activation of calcium/calmodulin-

dependent kinase type II alpha (CaMKIIα) and one of its main targets, the AMPA receptor (AMPAR), are critical for glutamate neurotransmission-induced neuroplasticity and for learning and memory. In addition, molecules that control the trafficking of AMPARs, such as cofilin (an actin depolarizing factor), have an essential role in the formation and remodeling of spines and dendrites, thereby modulating neuroplasticity. Consequently, we investigated the expression and phosphorylation status of CaMKIIα and GluA1 subunit of the AMPAR in cultured hippocampal neurons acutely treated with vortioxetine and examined the effects of chronic vortioxetine on expression and phosphorylation status of cofilin and GluA1 subunit of AMPAR in cortical synaptosomes of young and middle-age mice. Dissociated rat hippocampal cells (obtained from fetuses at embryonic day 18 and cultured for 21 days) were treated with vortioxetine, nefiracetam (CaMKIIα activator) or control for 1 h. Young and middle-aged female C57BL/6 mice were treated with vortioxetine-containing or regular chow for 1 month. The levels of total and phosphorylated CaMKIIα, GluA1 subunit of AMPAR and cofilin were measured by Western blotting and vortioxetine's effects were analyzed by 2-way ANOVA followed by post-hoc Tukey-Kramer tests. Acute vortioxetine increased phosphorylation of CaMKIIα without any effects on the total CaMKIIα protein level. This was accompanied by an increase in phosphorylation of GluA1 subunit of AMPAR at serine 845 without affecting phosphorylation at serine 831 or the total GluA1 protein level. In young mice, chronic vortioxetine increased cofilin phosphorylation without altering total cofilin protein level, and increased phosphorylation of GluA1 subunit of AMPAR at serine 845 without altering serine 831 or total GluA1 protein level. Our results indicate that vortioxetine modulates molecular targets related to neuroplasticity, which may elucidate the beneficial effects in cognitive function observed in clinical studies.

Title: Phosphorylation status of eIF4B S406 is a molecular switch in BC RNA-mediated translational control

Authors: *T. EOM[1], I. A. MUSLIMOV[1], S.-C. CHUANG[1], R. K. S. WONG[1,2], H. TIEDGE[1,2]; [1]Physiol. and Pharmacol., [2]Neurol., SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: Regulatory Brain Cytoplasmic (BC) RNAs repress translation at the level of initiation by interacting with eukaryotic initiation factors (eIFs) 4A and 4B. BC RNAs inhibit recruitment of the 40S small ribosomal subunit by directly competing with 18S rRNA for binding to eIF4B. However, the mechanism for reversible regulation of BC RNA-mediated translational control is not well understood. Electrophoretic mobility shift assays (EMSAs) indicated that phosphorylation of eIF4B at serine 406 (S406) increased the affinity of BC RNA binding. We observed that BC RNA-mediated translational control was modulated by the phosphorylation status of eIF4B S406. eIF4B S406 phosphorylation was significantly reduced upon stimulation with DHPG, an agonist of group I mGluRs, or bicuculline, an antagonist of $GABA_A$Rs. Mediated by protein phosphatase (PP) 2A, eIF4B S406 was dephosphorylated within less than 2 min following receptor activation. This dephosphorylation resulted in the release of BC RNAs from eIF4B and in a substantial increase of protein synthesis. Subsequent re-phosphorylation of eIF4B S406 enabled high-affinity binding of BC RNAs, causing translational repression. Our data indicate that the phosphorylation status of eIF4B S406 serves as a molecular switch in BC RNA-mediated translational control. It suggests a novel molecular mechanism that links neuronal activity to translational control.

Title: Identification of the newly synthesized protein required for synaptic plasticity in Xenopus laevis

Authors: *H.-H. LIU[1,2], W. SHEN[1,4], L. SCHIAPARELLI[1], D. MCCLATCHY[3], J. R. YATES, III[3], H. T. CLINE[1,2,3];

Abstract: Emerging evidence has shown the importance of newly synthesized proteins in long-term synaptic plasticity and memory formation. In an effort to uncover mechanisms of experience-dependent synaptic plasticity, we performed quantitative proteomic analysis using improved bio-orthogonal metabolic labeling (BONCAT), an unbiased method to label newly synthesized proteins, with mass spectrometric multidimensional protein identification (MudPIT) to identify candidates that undergo dynamic protein synthesis in response to visual conditioning in the visual system of *Xenopus laevis* tadpoles. From two independent experiments, we detect a large variety of proteins, which are annotated to multiple cellular organelles or compartments, and to many cellular functions, for example, proteasome 26S subunits, RNA-binding proteins and cytoskeleton proteins. This list of candidates, together with the follow up functional analysis, should help us uncover the molecular machinery participating in synaptic plasticity. In addition, we also used fluorescent noncanonical amino acid tagging (FUNCAT) to investigate the dynamic in local protein synthesis in response to visual conditioning and found that Fragile X mental retardation protein (FMRP), a negative regulator of protein translation, is important for local protein synthesis and is required to maintain the visual conditioning-induced behavioral plasticity.

Title: Role of FMRP bound miRISC at the crossroads of NMDAR and mGluR signalling

Authors: ***P. M. KUTE**[1,2], N. NEELAGANDAN[1], S. GOSH DASTIDAR[1], S. CHATTERJI[1,3], R. MUDDASHETTY[1];
[1]Inst. for Stem Cell Biol and Regenerative Med., Bangalore, India; [2]SASTRA Univ., Thanjavur, India; [3]Natl. Ctr. for Biol. Sci. (NCBS), Bangalore, India

Abstract: Activity mediated protein synthesis is a critical component of synaptic plasticity. NMDAR and mGluR mediated signalling are key constituents of synaptic plasticity both of which modulate synaptic protein synthesis. But how translation is specifically regulated downstream of either mGluR or NMDAR and their potential cross talk at the level of protein synthesis is not understood. Core objectives of this study is to characterize the common translation regulatory mechanism downstream of mGluR and NMDAR and then identify the unique components of this machinery which provides specificity. Fragile X Mental Retardation Protein (FMRP) is a known translation modulator that responds to mGluR signalling, the lack of which causes fragile X syndrome (FXS). FMRP regulates the expression of its target mRNAs by recruitment of microRNA induced silencing complex (miRISC) which can be reversed to facilitate translation by mGluR stimulation. Here we propose that FMRP-miRISC complex also regulates the translation downstream of NMDAR signalling. The composition of miRISC and its interaction with FMRP determines the translation status and specificity for mGluR and NMDAR signalling. We have identified MOV10 (an axillary component of miRISC) as a key determinant of this function. In synaptoneurosomal (SNS) preparation from Sprague Dawley (SD) rat (P30) brain cortex, downstream of NMDAR or mGluR signalling we observed contrasting association of MOV10 with miRISC and polysome. In case of NMDAR signalling, MOV10 dissociates from miRISC as measured by quantitative immunoprecipitation and moves to polysomes (as measured by polysome profiling) indicating translation of target mRNAs; whereas in mGluR signalling, MOV10 dissociates from polysomes and moves into inhibitory complex (miRISC) implying inhibition of target mRNAs. Immunostaining in cortical neuronal culture also shows reduced co-localization of AGO2 and MOV10 on mGluR signalling, consistent with the immunoprecipitation results. Interestingly, in Fmr1 KO rat SNS, MOV10 is completely absent in polysomes and hence lacks the NMDAR and mGluR mediated shift, bestowing a crucial role on FMRP for both these signalling. This result is further supported by our work in Neuro 2a cells, where siRNA mediated knockdown of FMRP shows a significant decrease in association of MOV10 with AGO2 and also lack of MOV10 in translating polysomes. These results indicate that MOV10 depends on FMRP to be associated with inhibitory complex of miRISC or with translating polysomes. We hypothesize that the composition of FMRP bound miRISC determines translation response of specific subset of mRNAs to different synaptic signals.

Title: Communication of pathway-specific circuit activity to the genome by dendritic translation of the immediate early gene Npas4

Authors: *S. BRIGIDI[1], P.-A. LIN[2], B. L. BLOODGOOD[1];
[1]Div. of Biol. Sciences, Neurobio. Section, Univ. of California San Diego, LA Jolla, CA;
[2]Neurosci. Grad. Program, Univ. of California San Diego, La Jolla, CA

Abstract: During learning, task relevant neurons must convert fleeting stimuli into stable modifications in connectivity and excitability that alter their output. Mechanisms that govern plasticity are executed over many time scales and the most enduring forms of plasticity require regulation of the genome. Inducible transcription factors (ITFs) are a subset of immediate-early genes that support learning by linking transient molecular signals with long-lasting changes in cellular function through activity-dependent changes in gene expression. Npas4, a bHLH-PAS domain ITF, is undetectable in quiescent neurons but is rapidly induced in response to membrane depolarization *in vitro* and learning-related sensory experiences *in vivo*. Experience-dependent Npas4 expression dramatically reorganizes inhibitory synapses along the somato-dendritic axis of CA1 pyramidal neurons (PNs), increasing somatic and decreasing dendritic inhibition. This suggests that Npas4 regulates neuronal functions immediately linked to excitation by recalibrating inhibition in discrete domains of the PN. However, the nature of excitatory signals that lead to Npas4 induction, and whether the genome is capable of differentiating between excitatory signals that originate from distinct regions of the PN remains unknown.
Here we identify two independent pathways that lead to Npas4 expression in CA1 PNs that have distinct kinetics and functional consequences. A one second train of action potentials (APs) is sufficient to induce the accumulation of Npas4 in the PN soma through a signaling pathway that requires Ca^{2+} influx through L-type voltage-gated Ca^{2+} channels, transcription, and translation. In addition, we identify a pool of Npas4 mRNA localized to PN apical dendrites that is rapidly translated in response to NMDA receptor signaling initiated by sub-threshold transmission at Schaeffer Collateral synapses. Npas4 protein produced in the dendrites is then trafficked to the nucleus where it regulates gene expression. Surprisingly, Npas4 forms distinct heterodimers with

other bHLH-PAS transcription factors in response to APs or synapse activation. As each heterodimer binds a preferred nucleotide sequence, we predict stimulus-specific heterodimers facilitate communication of pathway-specific information to the nucleus in order to regulate unique aspects of Npas4's cellular phenotype. Together, our findings suggest that Npas4 executes an excitation-to-inhibition transfer function that distinguishes APs from synaptic activity originating from a specific excitatory pathway, and represents a novel mechanism for communicating circuit-relevant information to the genome.

Title: Transcriptome profiling in hippocampal dendrites

Authors: ***S. FARRIS**, J. M. WARD, M. SAMADI, Y. WANG, S. M. DUDEK;
Natl. Inst. of Envrn. Hlth. Sci., Research Triangle Park, NC

Abstract: Several lines of evidence suggest that experience-dependent translation of mRNA in dendrites is required for the persistence of experience-dependent changes in the brain. This spatial restriction of mRNA to subcellular domains enables local regulation of protein synthesis in a synapse-specific manner. It is currently unknown whether different cell types express different complements of dendritic RNAs to regulate specific forms of synaptic plasticity. Synapses in hippocampal area CA2 differ from those in neighboring subregions in that they do not undergo typical long-term potentiation, a process that requires local protein synthesis. In fact, we found that even the maintenance of baseline synaptic transmission in CA2 may require dendritic protein synthesis, as translation inhibitors led to a decrease in postsynaptic responses in CA2, but not in CA1. These data suggest that local protein synthesis may play a critical role in gating synaptic plasticity in CA2 dendrites. To identify the RNA transcripts in CA2 and surrounding subregion dendrites (CA1, CA3 and DG), we used laser-capture microdissection on hippocampal sections from a mouse line that expresses green fluorescent protein in CA2. RNA was isolated from the cell bodies and dendrites of each subregion (N=3 adult male mice) and used to generate cDNA libraries for RNAseq. Libraries from each animal were eight-plexed and run on a single lane of the Illumina NextSeq500 instrument acquiring 100bp paired-end reads.

Reads were aligned to the mouse genome (mm10) using STAR. Differential gene expression was determined using DESeq2 and alternative splicing was assessed using DEXseq. Finally, Illumina NextBio analyses were used to identify enriched canonical pathways in dendrites.
We found that CA2 dendrites are enriched for unique mRNA transcripts compared to neighboring CA1, CA3 and DG. In particular, genes involved in lipid metabolism and the generation of energy were expressed at higher levels in CA2 dendrites than neighboring dendrites. In addition, plasticity-restricting mRNAs, such as *Pcp4, Rgs14, Ptpn5 and Necab2* were enriched in CA2 dendrites and validated using single molecule fluorescent in situ hybridization. Identifying molecules in CA2 dendrites may lead to novel therapeutic targets for disorders in which dendritic protein synthesis has gone awry, such as those in the autism spectrum.

Title: Beta-adrenergic receptors activation in conditional dendritic RNA transport

Authors: ***I. A. MUSLIMOV**[1], H. TIEDGE[1,2];
[1]Physiol. and Pharmacol., [2]Neurol., SUNY Downstate Med. Ctr., Brooklyn, NY

Abstract: In neurons, RNA transport plays an important role in synapto-dendritic protein synthesis. We previously reported that regulatory Brain Cytoplasmic (BC) 1 RNA is constitutively transported to dendrites where it operates as a repressor of local protein synthesis. ID3 and ID4 elements are phylogenetically derived from BC1 RNA by retroposition, and we asked whether such elements convey targeting competence to mRNAs that carry them. ID3-tubulin and ID4-tubulin reporter mRNAs were microinjected into somata of sympathetic neurons in culture that had been stimulated using agonists of alpha- or beta-adrenergic receptors (phenylephrine or isoproterenol, respectively). Following activation of beta-adrenergic receptors, injected reporter mRNAs were targeted to dendrites. Dendritic transport was not observed in the

basal state or following alpha-adrenergic activation. As a representative of an endogenous mRNA carrying an ID3 element, we selected CLN2 (ceroidlipofuscinosis, neuronal 2) mRNA. This mRNA was not delivered to dendrites in the basal state. However, CLN2 mRNA was transported along the dendritic extent following beta-adrenergic (but not alpha-adrenergic) receptor activation. Induced dendritic CLN2 mRNA transport was blocked in the presence of beta-adrenergic antagonist propranolol. The combined data indicate that beta−adrenergic activation signals to dendritic RNA transport.

Title: The kinesin motor protein KIF5B regulates RNA trafficking and dendritic spine morphogenesis in hippocampal neuron

Authors: *H.-L. CHAN, J.-D. HUANG, K.-O. LAI;
Sch. of Biomed. Sci., The Univ. Of Hong Kong, Hong Kong, Hong Kong

Abstract: Protein synthesis in neuron can occur locally near individual synapses of the postsynaptic neuron, which may serve to translate synaptic activity into the formation of persistent synaptic connections and mature dendritic spines. To achieve local protein synthesis, specific mRNAs must first be transported to the neuronal dendrites. The anterograde transport of selective cargoes, including mRNAs, protein complexes and organelles to distal dendrites, is carried out by the Kinesin Superfamily (KIFs) of molecular motors. Among them, the three members of the KIF5 family (KIF5A, KIF5B & KIF5C) are present in the ribonucleoprotein complexes (RNPs) that transport dendritic mRNAs. However, it is not clear whether individual KIF5 perform redundant or distinct functions in the transport of RNPs and the regulation of synapse structure. Here we performed time-lapse confocal imaging using the RNA dye SYTO 14

and the Mitotracker CMXRox to monitor the dynamics of RNPs in dissociated hippocampal neurons derived from wild-type or KIF5B heterozygous knockout mice. Consistent with previous studies, majority of the RNPs were stationary, and the motile RNPs exhibited discontinuous movement which was either oscillatory (bi-directional movement over short distances) or unidirectional (moving one direction over long distances). Interestingly, KIF5B heterozygous neurons contained significantly fewer stationary RNPs, and higher proportion of RNPs displayed unidirectional movement. We further found that knock down of KIF5B expression in rat hippocampal neurons using short hairpin RNA (shRNA) led to the loss of mature spines and a significant increase in the number of immature filopodia. These findings suggest that the kinesin KIF5B is crucial for the transport and docking of selective mRNAs, which may subsequently regulate the maturation of dendritic spines.

Title: A transcriptional program underlying homeostatic scaling

Authors: ***K. SCHAUKOWITCH**, A. L. REESE, S.-K. KIM, G. KILARU, J.-Y. JOO, E. T. KAVALALI, T.-K. KIM;
Neurosci., UT Southwestern Med. Ctr., Dallas, TX

Abstract: Homeostatic scaling allows neurons to maintain stable activity patterns by globally altering their synaptic strength in response to changing activity levels. Deficits in scaling have been seen in models of autism spectrum disorders and schizophrenia, implicating its importance in cognitive function. One mechanism by which this process occurs is through up- or down-

regulating surface AMPA receptors. Decreasing activity by blocking action potentials with the sodium channel blocker, TTX, leads to an upregulation in synaptic strength, as seen by increases in AMPA mediated mEPSCs. In the opposite way, increasing activity with the $GABA_A$ receptor antagonist, bicuculline, decreases mEPSCs. It was previously shown that the increase in mEPSC amplitude in response to TTX could be blocked by a transcription inhibitor, suggesting that transcription is necessary for the scaling response. However, very little is known about the genes whose transcription is directly regulated by activity suppression or the signaling mechanisms underlying the transcriptional control. Using RNA-Seq, we identified nearly 100 genes that were specifically upregulated in response to TTX. In particular, *Neuronal pentraxin-1* (*Nptx1*), previously shown to promote AMPAR clustering, was increased ~3 fold after 6h of TTX, and knockdown of this gene blocked the TTX-induced increase in mEPSC amplitudes. SRF is a key transcription factor in regulating *Nptx1* induction, and this induction is calcium-dependent, indicating the existence of an active pathway to control transcription. Taken together, our study defines a novel transcriptional program that is able to sense the absence of activity and coordinate the cell's response to globally increase synaptic strength.

Title: Npas4 is necessary for circuit homeostasis and plasticity in the mouse primary visual cortex

Authors: ***X. SUN**, S. F. COOKE, M. J. BERNSTEIN, R. W. KOMOROWSKI, M. F. BEAR, Y. LIN;
Brain and Cognitive Sci., MIT, Cambridge, MA

Abstract: Homeostatic regulation of synapses is key to maintaining the excitatory and inhibitory (E/I) balance of cortical circuits, upon which cortical function and plasticity depend. However, critical molecular and synaptic components that give cortical circuits the ability to constantly adjust to changing levels of activity are not well characterized. Here we examine the importance of Npas4, an immediate-early gene that has been shown to be involved in activity-dependent

modulation of GABAergic synapses, for maintaining circuit homeostasis and visual plasticity. Npas4 is strongly induced by visual stimuli in the mouse primary visual cortex (V1). Conditional deletion of Npas4 rapidly and drastically disrupted E/I balance in V1 by reducing the inhibitory tone. Consistent with the importance of E/I balance in visual learning, disruption of the V1 network resulting from the loss of Npas4 led to a deficit in stimulus-selective response potentiation (SRP), an *in vivo* visual learning paradigm that depends on synaptic plasticity. Our findings demonstrate that the activity-dependent pathway downstream of Npas4 is required for homeostasis and plasticity in the mouse visual cortex.

Title: Experience-dependent transcriptional regulation of inhibition in the CA1 microcircuit

Authors: *A. L. HARTZELL[1], K. M. MARTYNIUK[2], G. P. HIGERD[2], B. L. BLOODGOOD[2];
[1]Neurosciences, [2]Biol. Sciences, Section of Neurobio., UCSD, San Diego, CA

Abstract: The hippocampus is tasked with converting fleeting neuronal activity from a novel experience into a stable memory representation. One consequence of transient elevated activity is the expression of inducible transcription factors (ITFs), which can initiate gene programs that execute widespread and long-lasting changes in cell function. NPAS4 is an ITF that orchestrates the reorganization of inhibitory synapses along the somato-dendritic axis of a pyramidal neuron (PN), reducing dendritic inhibition while concurrently recruiting inhibitory synapses to the soma. This remodeling can profoundly affect the computations performed by the cell, allowing for a more plastic dendritic environment while simultaneously tuning the output of the neuron.

However, the interneuron (IN) subtypes from which the reorganized synapses originate are not known. Among the more than 20 IN subtypes in the mouse hippocampus, parvalbumin (PV)- and cholecystokinin (CCK)- expressing basket cells innervate the perisomatic domain of CA1 PNs. Inhibition provided by PV and CCK basket cells gate PN output in a fast and linear, or slow and modulatory manner, respectively. Synapses arising from PV versus CCK basket cells can therefore profoundly regulate either the timing or "mood" of the CA1 microcircuit, but it is poorly understood how experience remodels these individual synapse subtypes. We sought to determine the identities of the INs whose synapses undergo activity-induced, transcriptionally-regulated reorganization downstream of NPAS4 expression, and examine how this circuit change affects activity and plasticity of the CA1 microcircuit.
Using *in vivo* genetic manipulations and *ex vivo* electrophysiology, pharmacology, and anatomical techniques, we demonstrate that novel sensory experiences specifically result in the recruitment of CCK-basket cell synapses to the PN soma in an NPAS4-dependent manner, while PV basket cell synapses remain unchanged. Furthermore, deletion of NPAS4 from CA1 PNs significantly reduces depolarization-induced suppression of inhibition (DSI), a form of short-term plasticity expressed at CCK basket cell synapses. This has the potential to regulate the excitability and plasticity of the CA1 microcircuit through Npas4-dependent changes in CCK-mediated disinhibition of PNs. Together, our results suggest that novel sensory experiences increase the influence of CCK INs on the CA1 microcircuit through an NPAS4-dependent transcriptional program to drive PN plasticity. Ongoing experiments are further exploring how this IN-specific, experience-dependent circuit reorganization can affect the computations performed by the CA1 microcircuit.

Title: Deconstructing the relationship between neural activity patterns and Npas4-mediated gene expression

Authors: *P.-A. LIN[1], G. S. BRIGIDI[2], B. L. BLOODGOOD[2];
[1]Neurosciences, [2]Biol. Sciences, Neurobio. Section, Univ. of California San Diego, La Jolla, CA

Abstract: During learning, transient sensory inputs are processed into persistent changes in neuronal function and circuit connectivity. Gene regulation by inducible transcription factors (ITFs) plays a key role in facilitating this transformation. In comparison to other ITFs, such as Fos and Egr1, Npas4 is unique due to its selective induction by Ca^{2+} influx via membrane depolarization and not by other common signaling molecules such as cAMP, neurotrophins, and growth factors. Additionally, behaviorally-driven expression of Npas4 results in a dramatic reorganization of inhibitory synapses that are made onto CA1 pyramidal neurons (PNs), simultaneously decreasing inhibition at the proximal apical dendrites while increasing inhibition at the soma. This led us to hypothesize that Npas4 may be able to convey the origins and dynamics of excitatory signals to the nucleus, resulting in the regulation of distinct sets of target genes and providing a potential mechanism for the opposing plasticity observed at different inhibitory synapse populations. Excitatory signals generated in PNs can range in magnitude from bursts of action potentials (APs) to subthreshold EPSPs. Additionally, EPSPs convey information from many efferent pathways that are organized spatially along the somatodendritic axis of the neuron. To determine if Npas4 conveys information to the nucleus about the origins or intensity of a depolarizing signal, we prepared acute hippocampal slices from wild type mice and delivered brief, focal electrical stimulation of either the alveus or laminarly-restricted efferents in the CA1 region. These stimulation paradigms, in combination with appropriate pharmacology, generate antidromic APs in CA1 PNs or pathways-specific EPSPs, respectively. The CA1 region from equivalently stimulated slices was then microdissected and pooled for chromatin immunoprecipitation followed by deep sequencing (ChIP-Seq) of Npas4-bound genomic sites. Our results indicate that Npas4 regulates different target genes in response to APs or synaptic transmission in the proximal apical dendrites. Next we sought to determine if Npas4 also conveys information regarding the number, frequency, or duration of APs produced by a CA1 PN. Using a custom-built LED array, we optogenetically induced precise patterns of APs while blocking excitatory synaptic activity. We then used a combination of electrophysiology, immunohistochemistry, and ChIP-Seq to analyze the relationship between distinct spiking patterns and Npas4-mediated gene regulation. Our results indicate a novel role for Npas4 in communicating the spatial and temporal characteristics of excitatory activity to the nucleus.

Title: The role of activity-induced DNA breaks in synaptic plasticity, learning, and memory

Authors: *R. MADABHUSHI[1], O. KRITSKIY[1], F. GAO[1], T. X. PHAN[1], S. YAMAKAWA[1], T. GILLINGHAM[1], R. RUEDA[1], J. D. JAFFE[2], L.-H. TSAI[1];

Abstract: Neuronal activity triggers the rapid expression of immediate early genes that play important roles in experience-driven synaptic changes, learning, and memory. While immediate early genes are primed for rapid induction, the specific impediments to their expression under basal conditions, and the mechanisms that relieve these constraints are still poorly understood. Recently, we reported that activity-dependent stimulation of neurons triggers the formation of DNA double strand breaks (DSBs) in the promoters of a subset of immediate early genes, including *Fos*, *Npas4*, and *Egr1*. These activity-induced DSBs are generated by the type II topoisomerase, Topo IIβ, and we showed surprisingly that Topo IIβ-mediated DSBs facilitate the rapid induction of these aforementioned IEGs. Here, we utilized a conditional mouse model to delete *Top2b* in excitatory neurons in the forebrain of adult mice. We report that Topo IIβ activity is essential for the formation of neuronal activity-induced DSBs and IEG induction *in vivo*, and that mice lacking Topo IIβ show deficits in associative and spatial learning behaviors. In addition to this, we describe the mechanisms that regulate the formation of Topo IIβ-mediated DSBs in response to neuronal activity. Specifically, using quantitative mass spectrometry, we show that neuronal activity triggers the rapid dephosphorylation of Topo IIβ, and that Topo IIβ dephosphorylation stimulates activity-dependent DSB formation. Together, these results provide new mechanistic insights into the regulation of neuronal activity-dependent DSB formation, and elaborate the significance of activity-dependent DSBs in crucial neuronal functions, including synaptic plasticity, learning, and memory.

Title: Adult Notch signaling underlies the rewarding memory of alcohol in *Drosophila*

Authors: ***E. PETRUCCELLI**[1], M. FEYDER[2], R. MUSTER[2], N. LEDRU[2], K. R. KAUN[2]; [1]Neurosci., [2]Brown Univ., Providence, RI

Abstract: Alcohol use disorder is a chronic relapse disorder impelled by its cravings. Despite its global, financial and public health burden, available treatments are both limited and inadequate. Safe and effective treatment requires a comprehensive understanding of mechanisms underlying the persistent rewarding memories of intoxication that trigger alcohol cravings and drug seeking behaviors. *Drosophila melanogaster* are an ideal genetic model for studying alcohol-induced behaviors, learning and memory, and complex molecular pathways because of their genetic tractability and natural preference for alcohol. Recently, we demonstrated that flies display acutely aversive, but enduring appetitive memories for alcohol. These behaviors require proper dopaminergic signaling and Notch pathway regulation. We hypothesize that alcohol reward memory requires neuron specific Notch-induced transcriptional responses that alter dopamine-related gene expression. To explore this, we used spatiotemporal genetic tools, molecular analyses, and brain immunohistochemistry techniques. We found that adult Notch receptor expression was required for alcohol reward memory in the mushroom body, an associative central brain structure. Alcohol exposure resulted in Notch-induced transcriptional responses in the adult brain as revealed by a Notch reporter tool. Lastly, we investigated the possible targeting of genes associated with dopamine signaling by Su(H), the transcriptional regulator of canonical Notch signaling using ChIP-qPCR. Together with our knowledge of neuroanatomical circuitry and molecular networks, this research helps unravel neurogenic mechanisms leading to, and possible treatment of, alcohol addiction.

Title: Examination of stalled polysomes in protein-synthesis dependent long-term potentiation in hippocampal cultures.

Authors: ***K. GINZBERG**, M. ANADOLU, T. E. GRABER, W. SOSSIN;
McGill Univ., Montreal, QC, Canada

Abstract: Late long-term potentiation (L-LTP) differs from early LTP in its dependence on protein synthesis. This dependence begins soon after LTP induction and may, similar to mGLUR-LTD (Graber et al., 2013), depend on fast local protein synthesis that is independent of translation initiation, resulting from the reactivation of stalled polysomes. There is evidence L-LTP requires some translation initiation (Graber et al, 2013), but this does not rule out additional requirements for proteins produced from stalled polysomes as well. In the stalled polysome model, the rate-limiting step of translation (initiation) occurs before mRNA transport, and the incomplete peptide is transported in an inactive form to the dendrite, bound to the stalled ribosome. Upon reactivation, the stalled ribosome completes protein synthesis, allowing for the newly-translated proteins to function at the synapse. Stalled polysomes can be detected using a cellular run-off assay where new polysome synthesis is blocked using an initiation inhibitor, actively translating polysomes are run off, and the remaining 'stalled' polysomes are detected using ribopuromycylation; this is a technique where puromycin is used to detect ribosomes with nascent polypeptides, and emetine is used to trap the puromycylated peptide on the ribosome (David et al., 2013). Using this assay we have found that most polysomes in dendrites of hippocampal cultures are stalled (Graber et al, 2013)
To examine whether L-LTP requires release of stalled polysomes, we will use chemically induced L-LTP in hippocampal cultures. As this paradigm is not well established, we are comparing activating L-LTP with (i) low Mg^2+-Glycine (Fortin et al., 2010), (ii) Forsklin (Shao et al., 2012), and the combination of Low-Mg^2+-Glycine and Forskolin. We are examining both the production of proteins known to be increased after L-LTP (CAMKII, S6 and PKM zeta) and the effect of L-LTP induction on the number of stalled polysomes using ribopuromycylation

(Tsokas et al., 2007; Eom et al., 2014; Ouyang et al., 1999).
Staufen1 (Stau1) is a protein which binds to double-stranded RNA and plays an important role in transporting mRNA to the dendrites (Vessey et al., 2008); down-regulation of Stau1 blocks L-LTP (Lebeat et al., 2008). As we have recently found that Stau2 is required for the regulation of stalled polysomes in mGLUR-LTD (Lebeau et al., 2011), it is possible that Stau1's requirement for L-LTP is also through the regulation of a distinct class of stalled polysomes. We have developed a lentivirus to knockdown Stau1 in hippocampal cultures and will report if it is required for the production of stalled polysomes and the increase in proteins during L-LTP.

Title: A combinatorial code of immediate-early genes encodes salient experiences

Authors: *A. CITRI;
The Hebrew Univ., Jerusalem, Israel

Abstract: How an individual responds to a situation is a function of cumulative past experience. We are interested in identifying plastic changes induced in the brain by experience, and understanding how they modify behavior in the future. We focus on experience-dependent plasticity at the molecular level, aiming to identify signatures of transcriptional dynamics that are unique to the encoding of aversive or rewarding experiences in the mesolimbic and limbic brain areas. Our entry point to this study is the comparative investigation of acute or repeated rewarding and aversiveexperiences. For each experience, we assessed the induction of immediate-early genes (0,1,2,4 hrs following the experience) in multiple brain regions: Nucleus Accumbens, Dorsal Striatum, Prefrontal Cortex, Amygdala, Lateral Hypothalamus,

Hippocampus and Ventral Tegmental Area. We investigated the transcriptional response to different experiences, by assessing gene expression patterns in naïve mice and mice exposed to acute or repeated experiences. Unique and robust transcriptional programs were identified in response to distinct experiences to the extent that each experience could be described by a pattern of transcription of a subset of genes in relevant structures. Furthermore, the recent experience of individual mice could be decoded with above 94% efficiency, solely based on the transcriptional induction of a subset of genes in a subset of brain structures. Dramatic differences were revealed in the encoding of aversive vs rewarding experiences. We observed a strong linkage between different features of an experience and the activation of sub-patterns of transcription in specific brain regions. Naturalistic rewarding experiences showed a development of the transcriptional response with repetition, while aversive experiences demonstrated a diminishment of the transcription imprint upon repetition. Our results reveal that different experiences are encoded by unique transcriptional patterns. Gene expression in distinct brain structures, dependent on the context and quality of the experience, represents encoding that may lead to different behavioral outcomes in the future. We propose the initiation of a new field of research, “Behavioral Transcriptomics”, aimed at utilizing transcription as an approach for investigation of mechanisms of experience-dependent circuit plasticity.

Abstract: The brain cytoplasmic RNA BC1 is a long non-coding RNA known to be involved in neuronal translational control, partly via association with the Fragile X Mental Retardation Protein ribonucleoprotein complex. Absence of BC1 has been associated with altered glutamatergic transmission and impaired adaptive behavior. Here, we investigated the role of BC1 RNA in the primary somatosensory cortex, a well-defined system to explore the link between dendritic spine morphology and synaptic connectivity. We found that spine density and spine head size are abnormal in barrel cortex principal neurons of BC1 knock out (KO) mice. Consistent with these results, BC1 KO mice have larger excitatory postsynaptic currents and spontaneous activity than their wild type littermates in this cortical region, as evidenced by *ex vivo* and *in vivo* electrophysiology. In addition, neurons lacking BC1 RNA show increased basal protein translation and higher postsynaptic levels of several glutamate receptor subunits and associated structural proteins. Finally, we provide evidence that barrel cortex structural plasticity in response to whisker deprivation and novel object recognition are impaired in BC1 KO mice. These findings highlight the importance of this non-coding RNA in synaptic structure and function as well as experience-dependent plasticity and learning. Furthermore, our study provides a novel animal model to understand how spine dysmorphogenesis leads to alterations in synaptic transmission and behavior, which could be particularly relevant in the context of intellectual disabilities.

Title: Serum response factor regulates structural plasticity of dendritic spines during development.

Authors: *K. KALITA-BYKOWSKA, A. KRYSIAK, A. SUSKA, S. LESKI, L. KACZMAREK;
Nencki Inst. of Exptl. Biol., Warsaw, Poland

Abstract: Re-arrangement of neuronal networks plays an important role in proper circuitry formation. Dendritic spines' shape changes from thin elongated filopodia-like structures to stable mushroom dendritic spines during brain development. Serum Response Factor (SRF), one of the major transcription factors in the brain, plays a prominent role in regulating various programs of gene expression in the adult brain in response to stimulation. The aim of our study was to investigate potential novel SRF functions in the regulation of structural plasticity during brain development. We found that SRF protein expression change within the course of postnatal development of mouse hippocampus *in vivo*. SRF knockdown in hippocampal primary cultures resulted in increased number of filopodia-like protrusions and decreased number of mushroom spines with the general lack of changes in the overall density of dendritic spines. Moreover, spines of SRF knockdown neurons exhibited altered morphology, highlighted by increased length and area of filopodia-like and long spines. Furthermore, SRF-depleted neurons had lower level of surface AMPAR GluR1 subunit. We showed that the number of functional synapses and their activity was lower in SRF-depleted cells as shown by a reduction in the frequency and amplitude of miniature excitatory postsynaptic currents. These findings indicate that SRF regulates transcription of genes essential for synapse/spine formation and maturation during hippocampal development.

Title: Network dynamics of nociceptive processing in the anterior cingulate cortex

Authors: F. KASANETZ, M. SANTELLO, *T. NEVIAN;
Univ. of Bern, Bern, Switzerland

Abstract: The Anterior Cingulate Cortex (ACC) plays a central role in the interpretation and evaluation of the affective and emotional components of pain. Accumulating evidence indicates that abnormal neuronal plasticity and a resulting hyperactivity of the ACC is the cause for the manifestation of the emotional distress that characterizes chronic pain conditions. However, little is known on how the functional organization of ACC microcircuits is affected in chronic pain. Apart from its involvement in pain perception, the ACC is engaged in a variety of other cognitive and emotional processes such as working memory, inhibitory control, conflict monitoring, fear, attention, salience and reward expectancy. How neuronal populations in the ACC can be involved in such a diversity of functions is a matter of debate. One intriguing hypothesis would be that the ACC is composed of multiple sub-circuits mediating separate aspects of behavior. Here we addressed whether the ACC possesses specialized neurons that process nociceptive information and how this putative microcircuit organization is affected in chronic neuropathic pain. We also focused on the role and activity of dendritic sub-compartments of pyramidal neurons in information processing in the ACC. Using in vivo recording of spiking activity in the mouse ACC, we have identified a subpopulation of neurons that are activated in response to nociceptive stimulation. Interestingly, this “nociceptive neurons” showed a preferential increase in spontaneous activity during chronic pain, suggesting that ACC hyperactivity might be restricted to a sub-network of pain-related cells. In order to gain insight into the organization and plasticity of the ACC, we will present data combining in vivo two-photon calcium imaging of neuronal populations and dendritic sub-compartments with neuronal tracing and synaptic silencing techniques to uncover the functional properties and neuronal identity of ACC “nociceptive neurons” and its modulation by chronic pain.

Title: Exploring input-output relations of neurons *In vivo*

Authors: C. J. ROOME, *B. KUHN;
OIST Grad. Univ., Onna-Son, Okinawa, Japan

Abstract: Measuring input-output relations of single neurons in vivo is very important for understanding how the brain works. So far, the most complete input-output relations were measured in brain slices, which lack physiological input to dendrites and soma. Here we combine two-photon microscopy and electrophysiology to simultaneously measure dendritic voltage and calcium signals (inputs) and somatic output from Purkinje cells (PC) in vivo. To record dendritic voltage optically we labelled single PCs with the voltage sensitive dye ANNINE-6plus, using a chronic cranial window with access port (Roome and Kuhn, 2014). For dendritic calcium recording, adeno-associated viruses delivering the gene of the genetically encoded calcium indicator GCaMP6f, was injected prior to ANNINE-6plus labelling. Extracellular electrophysiology was also performed at the labelled PC soma to record their somatic activity. Combing techniques allows measurement of voltage and calcium changes in the PC dendrite and simultaneous electrical recording from the PC soma in the cerebellum of awake mice. By dissecting input-output relations at a single cell level within the intact brain, we aim to address important questions concerning neuronal computations in vivo.

Title: Glutamate-mediated plateau potentials studied by simultaneous multi-site dendritic sodium and calcium imaging

Authors: *S. D. ANTIC[1], K. MIYAZAKI[2], W. N. ROSS[2];
[1]Neurosci, UConn Hlth., Farmington, CT; [2]Physiol., New York Med. Col., Valhalla, NY

Abstract: Strong synaptic inputs generate glutamate-mediated plateau potentials in basal dendrites of cortical pyramidal neurons (Milojkovic *et al.*, 2004). Plateau potentials propagate into the soma, sometimes causing relatively large amplitude (~20 mV) sustained (~200 ms) somatic depolarizations, often accompanied by bursts of action potentials. Such dendritic plateau potentials are regenerative in nature and dependent on mixtures of activated conductances (AMPA, NMDA, Na^+ channels, voltage-gated Ca^{2+} channels (VGCC) and K^+ channels) in a process dubbed "spike-chain mechanism" (Schiller *et al.*, 2000). Because activation of one conductance can influence activation of other conductances through voltage and/or resulting ion fluxes (e.g. [Ca2+]i), it is difficult to determine the precise relative contribution and order of spikes in the dendritic spike-chain event based solely on the actions of selective channel antagonists on the spike waveform. One way to determine more information about the relevant dendritic currents is to observe concentration changes resulting from fluxes of ions to which receptors and channels are permeable. For example the influx of Na^+ reports activity of dendritic AMPA, NMDA and Na^+ channels, while the influx of Ca^{2+} reports activity of NMDA and VGCCs. In the present study we simultaneously monitored dendritic Na^+ and Ca^{2+} influxes during subthreshold and suprathreshold glutamate-mediated potentials. Simultaneous Na-Ca imaging (Miyazaki & Ross, 2015) was used to detect concentration changes in L5 pyramidal neurons in brain slices cut from (male and female) rat medial prefrontal cortex. [Na+]i changes were detected with either SBFI or ANG-2; [Ca2+]i changes were detected with either OGB-5N, OGB-1 or Bis-fura-2. Focal glutamate microiontophoresis was used to trigger plateau potentials. We observed Ca^{2+} transients from multiple locations along dendrites. The largest responses were at the input site and were blocked by APV. Application of VGCC antagonists reduced the Ca^{2+} signal beyond the input site. Na^+ transients were detected at the input site only. They persisted in the presence of TTX showing that they were receptor mediated. In many experiments most of the Na^+ signal remained after the addition of APV suggesting a strong AMPA receptor component in these responses.

Title: Somatic membrane potential modulates the propagation of dendritic spikes in CA1 pyramidal neurons

Authors: *T. BOCK, S. A. SIEGELBAUM;
Dept. of Neurosci., Columbia Univ., New York, NY

Abstract: Active signal propagation in the apical dendrites of pyramidal neurons (PNs) can amplify synaptic potentials, modulate action potential (AP) firing and contribute to synaptic plasticity. Dendritic calcium spikes have been thoroughly investigated in layer 5 PNs in acute cortical slice preparations, where they readily propagate to the soma and help induce burst firing of APs. Although in vivo recordings from hippocampal CA1 PNs suggest that dendritic spikes can trigger burst firing in the soma, recordings in acute slices indicate that these spikes propagate poorly to the soma, and so have only a limited impact on somatic output. As the in vivo resting potential is significantly depolarized relative to ex vivo conditions, we investigated the hypothesis that the resting potential can influence the efficacy of dendritic spike propagation. We performed simultaneous dual whole cell recordings from the soma and the distal apical dendrites of CA1 PNs in acute hippocampal slices. The propagation of dendritic spikes triggered by current injection or synaptic stimulation was strongly modulated by the somatic membrane potential. When the resting potential of the soma was depolarized, the efficacy of propagation was markedly increased. Depolarizing the resting membrane potential from its normal ex vivo value of -70 mV to its in vivo value of -55 mV increased the somatic depolarization produced by a dendritic spike by 398 % (± 69 %), which can now induce somatic burst firing. This effect is likely mediated by the inactivation of dendritic A-type potassium channels, as the application of 5 mM 4-AP enhanced the propagation of dendritic spikes at the normal negative resting potential. Furthermore, this modulation of dendritic spike propagation has a profound impact on plasticity mechanisms that require dendritic spikes. Input time dependent plasticity (ITDP) is induced by the precise pairing of entorhinal cortex inputs to distal dendrites with Schaffer collateral inputs to proximal dendrites. Normally, ITDP requires 90 paired stimuli at 1 Hz, which leads to the firing of dendritic spikes. However, somatic depolarization facilitates the propagation of dendritic spikes during synaptic pairing and also facilitates the induction of ITDP to <40 paired events. These experiments show the importance of somatic resting membrane potential for the electrical coupling of subcellular compartments, such as the distal apical

dendrite and the soma. As CA1 PNs are much more depolarized *in vivo*, due to constant low-level synaptic input, than in acute slices, we hypothesize that dendritic spikes have a much larger impact on plasticity mechanisms and on AP firing, under physiological conditions.

Title: Synaptically activated sodium changes in dendritic spines of rat hippocampal pyramidal neurons

Authors: K. MIYAZAKI, *W. N. ROSS;
New York Med. Col., Valhalla, NY

Abstract: Measurements of physiologically activated $[Na^+]_i$ changes can reveal information about functions that $[Ca^{2+}]_i$ changes are not directly sensitive to. One example is synaptic activation of AMPA receptors, which are permeable to Na^+ but not to Ca^{2+} in many neurons. A second example is activation of voltage gated Na+ channels (VGSCs), which usually are detected optically by monitoring $[Ca^{2+}]_i$ changes caused by the associated voltage changes. To examine these kinds of events in hippocampal slices we injected individual pyramidal neurons with pairs of Na^+ and Ca^{2+} indicators and measured fluorescence from both indicators simultaneously at high speed (250 Hz in each channel) with a CCD camera (Miyazaki and Ross, 2015). Usually we measured $[Na^+]_i$ changes in one channel and $[Ca^{2+}]_i$ changes in the other channel. Sometimes, to enhance the $[Na^+]_i$ signal, we used two different Na^+ indicators that generated fluorescence changes of opposite sign in response to a $[Na^+]_i$ increase. This procedure enhanced the S/N of the response and eliminated common mode noise from movements. Synaptic shocks in the Str. radiatum at low intensity evoked epsps without spikes. These responses were sometimes associated with both $[Na^+]_i$ and $[Ca^{2+}]_i$ changes that were localized to a few microns on the dendrite. To enhance the success rate we used paired stimuli at 5 ms intervals. This improvement was probably due to facilitation since greater shock separation clarified that the signal came from the second stimulation. APV+CPP blocked most of the localized $[Ca^{2+}]_i$ increase but had only a small effect on the $[Na^+]_i$ increase, indicating that entry through NMDA receptors was responsible for most of the $[Ca^{2+}]_i$ increase, while entry through

AMPA receptors was responsible for most of the $[Na^+]_i$ increase. Including QX-314 in the pipette did not block the $[Na^+]_i$ increase showing that little signal was due to entry through VGSCs. This result was consistent with the finding that backpropagating spikes alone evoked only small $[Na^+]_i$ increases in the dendrites. Since other experiments have established that synaptically activated AMPA receptors are located exclusively on spine heads we conclude that the localized $[Na^+]_i$ increases in the presence of APV+CPP results from Na^+ entry into spines. In many cells the rise time of the $[Na^+]_i$ increase at the center of the response was less than 10 ms, while the rise time at locations several microns away was slower, suggesting Na^+ entry in the spine and diffusion to sites on the dendrites. The decay time at many spines was 50 ms or less. Using a simple model for diffusion (Svoboda et al., 1996) this fast recovery suggests a low neck resistance in these spines.

Abstract: The basal and apical oblique dendrites receive a significant proportion of the synaptic input to neocortical layer 5 (L5) pyramidal neurons. When measured somatically, each individual input is quite small. However, when several synaptic inputs onto a single dendritic branch are clustered in time, they combine to trigger a much larger amplitude, supralinear response. Such nonlinear integration is critical for information processing and signal propagation within the cortical circuit. We compared branch integration in the basal dendrites and the proximal apical obliques for two different L5 pyramidal neuron populations in the motor cortex using the BAC

mouse lines: Etv1-egfp (etv1) and Thy1-yfp-h (thy1). Spines were activated by photolyzing MNI-glutamate with brief focused pulses of light (200 us at 720 nm). Individual spine responses were calibrated to match previously established equivalent amplitude and rise times of sucrose-evoked responses for each neuron type. To characterize branch integration, we selected multiple (~30) spines evenly distributed along a single dendritic branch. For both thy1 (n = 17) and etv1 (n = 13), near-synchronous activation triggered supralinear responses of equivalent amplitudes and rise times. Furthermore, thy1 and etv1 dendrites did not require a significantly different minimum number of spines to trigger a supralinear event. However, the half-widths and thus the area of these responses were significantly greater in the etv1 neurons (events in etv1 neurons were 61% wider, 77% greater in area). These data suggest that recruitment of active events in the thin dendrites of etv1 neurons may exert longer-lasting and thus a more profound effect upon action potential firing. We next tested how much temporal clustering was necessary to produce supralinear events. For all dendritic compartments in both neuron types some temporal clustering was necessary: spine stimulation separated by > 5 ms (200 Hz), produced a voltage response identical to the linear sum. But the sensitivity to temporal clustering differed depending upon the neuron type and dendritic compartment. Thy1 basal dendrites exhibited a threshold-like sensitivity to temporal clustering. In contrast, the amplitude of supralinear responses in etv1 basal dendrites and thy1 proximal apical obliques increased with stimulation frequency in a graded manner. Thus the input sensitivity and the output response both depend upon the dendritic compartment and the neuron type in question. As such, information processing by these different units may be expected to be distinct.

Title: Dendritic NMDA spikes: from full-blown to graded boosting supralinearities. What causes the switch?

Authors: ***F. BRANDALISE**, U. GERBER;
Brain Res. Inst., Univ. of Zurich, Zuerich, Switzerland

Abstract: The recent demonstration that dendritic spikes are also generated *in vivo* (Gambino et al., 2014; Grienberger et al., 2014; Palmer et al., 2014; Bittner et al., 2015; Sheffield & Dombeck, 2015) has led to renewed investigation of their roles in dendritic computation for LTP induction (Chicon & Gan, 2015; Kim et al., 2015) and neuronal up-down state (Smith et al., 2013; Oikonomou et al., 2014). Among the various types of dendritic events, NMDA spikes are of particular interest because of their association with input timing-dependent synaptic plasticity (ITDP). Interestingly, an examination of input-output data shows that NMDA spikes can present either as full-blown spikes with a distinct threshold (Schiller et al., 2000; Major et al., 2013) or as events with graded amplitudes (Branco & Hausser, 2011). At present, the mechanisms underlying this difference remain unclear. We addressed this question at CA3 recurrent synapses where we induced associative LTP by repetitive pairing of a CA3-CA3 input followed by a mossy fiber input (Brandalise & Gerber, 2014). The amount of the potentiation decreased as a function of the distance between the mossy fiber and the CA3 recurrent inputs. We then repeated this protocol, but after inducing LTP at the mossy fiber input. In this case, we observed that at distal CA3 recurrent synapses the probability of evoking an NMDA spike was increased, as was the amount of LTP. At proximal synapses, however, although the number of NMDA spikes also increased, additional potentiation did not occur. Further analysis revealed that the NMDA spikes at non-potentiated synapses manifested as full-blown events, whereas NMDA spikes at already potentiated synapses turned into graded amplitude events. We then tested the hypothesis that a change in the synaptic AMPA/NMDA receptor ratio is responsible for the difference in the NMDA spike response. We therefore induced LTP at CA3 recurrent synapses employing a standard spike timing-dependent LTP protocol (STDP), which is known to increase the AMPA/NMDA receptor ratio (Debanne et al., 1998). We found that an increase in this ratio favored the generation of graded NMDA spikes. Subsequent application of an STDP LTD protocol converted the graded dendritic supralinearity back to full-blown NMDA spikes. These findings indicate that the initial state of potentiation of a synapse is a key factor determining whether NMDA spikes are induced as graded or as full-blown responses. This phenomenon may represent a homeostatic mechanism that serves to curtail excessive potentiation of synapses. Thus, NMDA spikes can act not only as causal triggers of synaptic plasticity but also as modulators of neuronal up-down state.

Title: Dendritic spikes determine input selectivity in pyramidal cells

Authors: L. GOETZ, M. R. GROEN, *A. ROTH, M. HAUSSER;
Univ. Col. London, London, United Kingdom

Abstract: Neurons compute by nonlinearly transforming spatiotemporal patterns of synaptic input into action potential (AP) output. Features of this input-output transformation during sensory processing in visual cortex (V1) include bursts of spikes riding on dendritic plateau potentials (Smith et al., Nature 2013). However, it is unclear which spatiotemporal patterns of synaptic inputs generate these local spikes and underlying plateaus, and how they in turn contribute to the initiation of APs. To address this issue quantitatively, we constructed a model of the presynaptic input received by a layer 2/3 pyramidal neuron during visual stimulation with drifting gratings, using experimental data on the statistics of spontaneous and sensory-evoked APs in neurons of mouse V1 and their synaptic connectivity. We make the simplest possible (and conservative) assumption that synaptic inputs are independent of each other, and randomly distributed in space over the postsynaptic dendrites as well as randomly activated in time. We use our presynaptic input model to drive a detailed active compartmental model of a postsynaptic layer 2/3 pyramidal neuron that satisfies an extensive set of constraints from experiments *in vitro* and *in vivo*.

This model successfully recapitulates the *in vivo* experimental data, generating bursts of fast local dendritic spikes, which are associated with dendritic plateau potentials. Both fast spikes and plateau potentials are heterogeneous in amplitude and time course, and depend primarily on sodium channel and NMDA receptor activation, respectively. We measured the distribution of the number of synaptic inputs required to trigger a fast local dendritic spike or a plateau potential, and how this number depends on the synaptic weights of the synapses involved. We find that the input patterns triggering dendritic regenerative events are sparse, and in some cases a single strong input synapse can trigger fast local spikes. Next, we established global conditions under which fast local spikes and NMDA plateaus influence neuronal output tuning. Specifically, we demonstrate the causal effect of fast local spikes and plateau potentials on orientation selectivity of AP output by selectively switching off the voltage dependence of the underlying conductances.

To conclude, we provide a quantitative prediction of numbers, strengths and spatiotemporal patterns of synaptic inputs generating dendritic spikes *in vivo*. Our model mechanistically explains how differently tuned synaptic inputs, which are distributed randomly over the dendritic tree, can give rise to orientation-tuned dendritic spikes, and in turn to the stimulus selectivity of axonal output.

Title: Rostro-caudal gradient of the dendritic integrative properties of layer 5 pyramidal neurons across the primary visual cortex

Authors: L. N. FLETCHER, *S. R. WILLIAMS;
Queensland Brain Inst., Brisbane, Australia

Abstract: The thickness of the neocortex varies over the neocortical mantle, a property that determines the size of the dendritic arbor of pyramidal neurons. In order to preserve canonical cell-class properties across the neocortex, the electrical architecture of the dendritic arbor must parallel such morphological changes. The conservation of the integrative properties of a defined class of neuron with dendritic size has, however, not been directly explored. Here we use high-resolution anatomical reconstruction, multi-site somato-dendritic electrophysiological recordings and computational modelling approaches to demonstrate that the physical size, electrotonic architecture, and mode of dendritic integration of layer 5B pyramidal neurons vary as a gradient across the rostro-caudal axis of the Wistar rat primary visual cortex. Our findings reveal that the integrative capacity of layer 5B pyramidal neurons transforms from multi-compartment, layered computations, to compact axo-somatic integration across the primary visual cortex. These data challenge the view that neocortical neuronal populations carry out canonical computations.

Abstract: Sharp wave-ripple (SPW-R) complexes is driven by an interaction between hippocampal excitatory pyramidal cells and inhibitory neurons. A SPW event is the most synchronous rhythm of the hippocampus where only five to ten percent of the pyramidal cell population is activated. During network activity synaptically activated dendritic segments can be participate in the neuronal engram. In our previous studies demonstrated the existence of dendritic calcium spikes in fast spiking parvalbumin interneurons (FS-PV INs) during sharp wave-ripple (SPW-R) activities. Until now, the dendritic integration mechanisms of the hippocampal pyramidal neurons (PYR) during SPW-R remain elusive. In this work we present multiple 3D, acousto-optical, two-photon laser-scanning technologies to monitor neuronal activity at different scales with genetically-encoded calcium indicators in a near-cubic-millimeter scan range (up to 700 × 700 × 1,400 μm3), with a high scanning speed (up to 1 Mhz), with high (<500 nm) resolution in the center core, and less than 1.9 x 1.9 x 7.9 μm3 resolution throughout the whole scanning volume. We used volumetric random-access calcium imaging of spontaneous activity from hundreds of neurons. We applied 3D trajectory scanning technique to measure multiple dendritic segments in vivo with motion compensation possibility. Finally we introduced an expansion of trajectory scanning technique to monitor the activity from more than 100 cells in vivo while obtaining information for motion correction.

Title: Dendritic morphology of corticospinal and crossed-corticostriatal neurons in mouse primary motor cortex

Authors: *B. A. SUTER[1], S. A. NEYMOTIN[2,4], G. M. G. SHEPHERD[5], W. W. LYTTON[3,6]; [1]IST Austria / Jonas Group, Klosterneuburg, Austria; [2]Physiol. & Pharmacol., SUNY Downstate, Brooklyn, NY; [3]Physiol. & Pharmacol., SUNY Downstate, Brooklin, NY; [4]Neurosci., Yale University, Sch. of Med., New Haven, CT; [5]Physiol., Northwestern University, Feinberg Sch. of Med., Chicago, IL; [6]Kings County Hosp. Ctr., Brooklyn, NY

Abstract: In neocortex, layer 5 is home to at least two types of pyramidal neurons, which can be distinguished by their projection targets - with roughly half projecting to subcerebral targets (pyramidal-tract, PT), including the spinal cord, and the rest extending axons only within the ipsi- and contra-lateral telencephalon (intratelencephalic, IT). These classes differ in intrinsic electrophysiology as well as local and long-range synaptic connectivity. They also differ in dendritic morphology, with PT neurons forming a “thick tuft” in layer 1, while IT neurons have “thin” tufts, or none at all. In rat frontal cortex, a quantitative analysis found additional characteristic differences between classes, and a sublaminar differentiation within ITs (Morishima & Kawaguchi, 2006). In mouse motor cortex, the quantitative dendritic differences between these classes have not been fully characterized, especially in the non-tuft regions. Previously, we found that PT dendrites (N=24 corticospinal neurons) are very uniform, with a constant fraction (~25%) in the tuft, independent of soma depth within layer 5B. Notably, about 65% of PT dendrites are located peri-somatically, where synapses are electrotonically closer to the soma. We thus wished to quantitatively compare the dendritic length-density across PT and IT populations, to ascertain (a) the relative density of peri-somatic dendrites, and (b) whether IT-type dendrites form a homogenous pattern, as is the case for the PT population.
We generated three-dimensional dendritic reconstructions of retrogradely-labeled ITs (N=17 crossed corticostriatal neurons) and analyzed them for length-density and branching patterns. We find that PTs have more dendrite than ITs in all compartments. PT dendrites are ~2x longer, with the most dramatic difference in the tuft (7.5x). In ITs the tuft length decreases as a function of soma depth - the deepest ITs lacking any tuft. Peri-somatic length-density is 1.5x greater in PT than in IT, and in part because PTs form a greater number of basal root branches.
Together, these findings demonstrate a combination of projection-specific and sublaminar dendritic patterning, leading to significant differences in the cortical volume sampled by individual pyramidal neurons, and the density with which this space is sampled, by both the apical tuft and peri-somatic dendritic compartments.
We used whole-cell somatic current-clamp recordings of the reconstructed neurons to generate NEURON models for both cell types via evolutionary optimization algorithms. We plan to use these models to investigate the contribution of dendritic morphology to the diversity of firing responses observed in layer 5.

Title: Schizophrenia as a disorder of cellular excitability: Insights from computational models of cortical neurons and cardiac pacemaker cells

Authors: *T. MÄKI-MARTTUNEN[1], G. HALNES[3], A. DEVOR[4], G. T. LINES[5], A. G. EDWARDS[5], A. TVEITO[5], A. WITOELAR[2], F. BETTELLA[2], S. DJUROVIC[2], Y. WANG[2], A. M. DALE[4], G. T. EINEVOLL[3], O. A. ANDREASSEN[2];

Abstract: Schizophrenia (SCZ) is a highly heritable mental disorder with a high burden of morbidity and large social impacts. Proposed disease mechanisms range from altered brain structure to deficits in synaptic transmission and immune system functions. One of the generic hypotheses addresses SCZ as a disorder of cortical excitability (O'Donnell 2008, *Cortical Deficits In Schizophrenia*, Springer). Altered membrane excitability as a disease mechanism is supported by a recent genome-wide association study that revealed 108 SCZ-associated genetic loci, many of which implicate genes encoding ion channels and Ca^{2+} transporters (Ripke et al. 2014, *Nat Gen* 45.10).
Although SCZ symptoms are primarily related to brain and cognition, SCZ patients also have an elevated risk of cardiac dysfunction. Part of the risk is inflicted by long-term use of antipsychotics, while part could be of genetic origin (Andreassen et al. 2013, *Am J Hum Genet* 92.2; Fujii et al. 2014, *PLoS ONE* 9.6: e98555). The elevated risk manifests in increased mortality rates among the patients, which prevail even when corrected for the increased numbers of deaths caused by accidents and suicide (Brown 1997, *Br J Psych* 171.6).
In this work, we employ biophysically detailed computational models of cortical neurons and cardiac pacemaker cells to study the contribution of SCZ and cardiac disease-associated genes to cellular excitability and functioning of these cells. We focus our analyses on two central cell

types: layer V pyramidal cells (L5PCs) in the cortex and sinoatrial node cells (SANCs) in the myocardium. The apical tuft of an L5PC is considered a biological substrate for cortical associations providing high-level context for low-level (e.g., sensory) inputs that arrive at the perisomatic compartment, and the ability of L5PC to integrate these inputs has been proposed as one of the mechanisms that could be impaired in hallucinating patients (Larkum 2013, *Trends Neurosci* 36.3). The SANCs, in turn, have a key role in controlling heart rate as the primary pacemakers of the mammalian heart. We show that subtle variants of SCZ-associated genes (modeled as in Mäki-Marttunen et al. 2016, *Biol Psych: Cogn Neurosci Neuroim* 1, 49-59) cause alterations in the L5PC ability to integrate apical and perisomatic inputs. Moreover, we show that these genetic variants affect electrical excitability of both L5PCs and SANCs, but often in opposite directions. Our results provide a plausible mechanistic explanation for the shared genetic etiology between SCZ and cardiac disease. In the future, this type of modeling approach may contribute in the development of the next generation antipsychotics that are free from cardiac side effects.

Title: Down-regulation of TrkB expression and signaling by the anti-convulsant drug valproic acid.

Authors: *S. DEDONI, M. C. OLIANAS, P. ONALI;
Univ. of Cagliari, Dept Biomed. Sci., Cagliari, Italy

Abstract: Several studies have shown that the anti-convulsant and mood-stabilizer drug valproic acid (VPA) can regulate the levels of brain-derived neurotrophic factor (BDNF) both in brain and cultured neural cells, but relatively little is known on whether VPA can affect the neuronal responses to BDNF. In the present study we investigated the effects of VPA on the expression and signaling of the BDNF receptor TrkB in retinoic acid-differentiated SH-SY5Y human

neuroblastoma cells and primary cultures of mouse cortical neurons. We found that prolonged exposure (24 h) of SH-SY5Y cells to VPA (1 mM) inhibited BDNF-induced phosphorylation of different signaling molecules regulated by TrkB, including Akt, GSK-3β and PLCγ1. The VPA inhibitory effects were associated with down-regulation of TrkB expression and inhibition of BDNF-induced transphosphorylation of TrkB. Similar results were obtained in mouse primary cortical neurons, where VPA (1 mM) reduced the TrkB protein levels and inhibited BDNF-induced Akt activation. The effects of VPA appeared to be specific for TrkB, as in SH-SY5Y cells the drug failed to affect TrkA levels and enhanced the expression of the common neurotrophin receptor p75-NTR. In agreement with its ability to inhibit histone deacetylases (HDACs), VPA markedly increased the acetylation of histone H2B at Lys5. Interestingly, the VPA inhibitory effect on BDNF signaling and TrkB expression was mimicked by other HDAC inhibitors, such as sodium butyrate, trichostatin A and MS-275, but not valpromide, a VPA derivative which did not enhance histone acetylation, indicating the implication of epigenetic mechanisms. As BDNF overactivity may play a role in the patogenesis of temporal lobe epilepsy and mania, the present study suggests that down-regulation of TrkB may contribute to the anticonvulsant and mood-stabilizing actions of VPA.

Title: Inhibition enhances rate and phase coding of place in hippocampal CA1

Authors: ***C. GRIENBERGER**, A. D. MILSTEIN, K. C. BITTNER, S. ROMANI, J. C. MAGEE;
Janelia Farm Res. Campus, Ashburn, VA

Abstract: Recent work suggests that all CA1 principal neurons receive a broad range of spatially tuned synaptic input that encodes for all relevant features of an environment. This arrangement is advantageous in that it provides a high degree of flexibility for place cells to acquire or add new place fields through rapid input strength changes. However, it can also be a cause of noise, potentially degrading the accuracy of the hippocampal place code. How, then, does a place cell maintain selectivity for particular locations? Here, we examined the ability of inhibitory input to

reduce the impact of broadly tuned excitatory input on the spatially tuned activation of place cells by performing whole-cell recordings of CA1 pyramidal neurons and interneurons on head-fixed mice running on a linear track treadmill. Using this approach, we found that unlike pyramidal neurons, hippocampal interneurons lack spatial modulation of their subthreshold membrane potential, which is also reflected in the lack of place specific action potential firing. Next, using optogenetic hyperpolarization of these interneurons (by Arch expression in VGAT-ires-cre mice and Gad2-ires-cre mice), we found that a constant level of broadly tuned synaptic inhibition (1) enhances the spatial tuning of CA1 place cells by selectively countering out-of-field inputs, (2) helps maintain the place field location by controlling the occurrence of dendritic plateau potentials and (3) reduces the impact of out-of-field inputs on the phase of the intracellular oscillations that drive theta phase precession in CA1 place cells. Finally, we turned to a biophysically detailed simulation of the hippocampal microcircuit incorporating our experimental findings to investigate the mechanisms underlying the effect of inhibition. Taken together, our results demonstrate that inhibition greatly contributes to the sparse structure of the hippocampal network activity by controlling for the relatively broad tuning of spatial inputs that the CA1 microcircuit receives from its afferent brain areas.

Abstract: Starburst amacrine cells are a critical component of the direction selective circuit in the retina. They are axon-less inhibitory interneurons, and therefore starburst amacrine cell dendrites contain both input and output sites. These dendrites present an opportunity to examine the precise role of functional sensory input location on dendritic computations. Using visual receptive field mapping, glutamate uncaging, two-photon Ca^{2+} imaging, and genetic labeling of putative synapses, we identified a unique arrangement of excitatory inputs and inhibitory release sites on starburst amacrine cell dendrites: excitatory inputs are skewed away from release sites. By comparing computational simulations with Ca^{2+} transients recorded near release sites, we show that this anatomical arrangement of inputs and outputs supports a dendritic mechanism for computing motion direction. Direction-selective Ca^{2+} transients persist when lateral inhibition is blocked by a GABA-a receptor antagonist, though directional tuning is reduced. These results indicate a synergistic interaction between dendritic and circuit mechanisms for generating direction selectivity. We explore the role of the dendrite-intrinsic and circuit-level components in the velocity-tuning of release sites. Our study highlights the important role of functional input location in the computations neurons are able to perform.

Title: Role of synaptic amplification in spatial selectivity in a biophysical model of the CA1 microcircuit

Authors: *A. D. MILSTEIN, C. GRIENBERGER, J. C. MAGEE, S. ROMANI;
Hhmi/Janelia Farm, Ashburn, VA

Abstract: Recent work suggests that CA1 place cells receive spatially tuned synaptic input corresponding to a broad range of locations in physical space, endowing place cells the flexibility to acquire spatially selective receptive fields in many locations through the plastic tuning of synaptic weights. However, this predicts a high degree of spatial and temporal synchrony in the pattern of presynaptic activity that a place cell receives, even at locations outside of its spatial receptive field, which is expected to engage presynaptic facilitation and postsynaptic amplification mechanisms. How, then, does a place cell maintain selectivity for locations with higher synaptic weights or increased input density? Here we present a biophysically detailed model demonstrating a role for broadly tuned synaptic inhibition in sharpening the spatial selectivity of CA1 place cells by suppressing membrane fluctuations driven by voltage-dependent amplification in spines and dendrites, consistent with experimental data from in vivo intracellular recordings. We also compare and contrast the features of place fields constructed by three alternative mechanisms: biased synaptic weights, biased input density, and spatial clustering of temporally correlated inputs on dendritic branches.

Abstract: Normal hippocampal operation relies on inputs from the medial septum. In turn, output from certain GABAergic neuron types of the hippocampus forms an extensive feedback to the medial septal network. These hippocampo-septal (HS) neurons receive numerous excitatory inputs from pyramidal cells, thus, they are positioned to control the septo-hippocampal connection as a function of hippocampal activity. However, there are mainly speculations about the role of the HS feedback in the regulation of hippocampal processes. In order to investigate the function of this pathway, we inactivated the HS fibers locally in the medial septum in freely behaving animals. The left and right hippocampus of somatostatin-Cre mice were transduced by a rAAV construct that Cre-dependently expresses the chloride-selective chimaeric channelrhodopsin SwiChR and YFP or only YFP as control. Optic fibers for illumination were implanted close to the medial septum, and hippocampal activity was monitored at high spatial resolution along the septotemporal axis by multishank silicon probes. In some experiments, medial septal units were also recorded using optic fiber-equipped silicon probes. The effect of HS inactivation was tested in natural sleep, linear track running, open field exploration and urethane anesthesia. Our preliminary data show that HS inactivation increases the power of theta in novel environment exploration, whereas in home cage, theta is not affected. We also characterize the effect of the HS feedback on the temporal coordination of theta across hippocampal layers and subfields as well as on the correlation pattern of concurrently recorded medial septal units.

Abstract: The alpha rhythm is the most ubiquitous graphoelement in the human EEG during quiet wakefulness; however, its cortical generators are still poorly characterized, especially in humans. Here, we use a combination of simultaneous macro (ECoG) and microelectrode (laminar) recordings in humans to measure which cortical layers and areas give rise to the human alpha rhythm. Although different cortical areas had distinct laminar generators of alpha activity, alpha oscillations tended to be generated in superficial and granular cell layers. Superficial layers receive diffuse matrix projections from the thalamus, whereas granular cortex receives specific, core thalamocortical afferents. This implies that thalamocortical projections play a key role in the generation of the human alpha rhythm. In some subjects, alpha phase modulated multi-unit activity in specific cortical laminae, providing unambiguous evidence that alpha exerts phasic inhibition and excitation in humans. We also discovered putative single units which were weakly (but significantly) phase-locked to ongoing and task-evoked alpha activity, directly demonstrating that alpha activity modulates neural firing. These findings provide insight into the microphysiology of the human alpha rhythm, as well as the mechanisms of how alpha phase impacts cortical processing and perception.

Title: Boosting occipital alpha power by transcranial alternating current stimulation at the second harmonic

Authors: *S. FARA[1,2], J. MCINTOSH[1,2,3], H. CHOI[1,2], C. MEHRING[1,2];
[1]Bernstein Ctr. Freiburg, Freiburg, Germany; [2]Fac. of Biol., Univ. of Freiburg, Freiburg, Germany; [3]Bioengineering, Imperial Col. London, London, United Kingdom

Abstract: Transcranial alternating current stimulation (tACS) has been previously shown to interact with oscillatory brain activity. This interaction is thought to originate from entrainment of neural oscillators with an intrinsic frequency close to the applied tACS frequency, or from neuronal plasticity. To date, investigation of these hypotheses in human subjects has been limited by the technical challenge of monitoring brain activity during tACS, due to the electromagnetic artefact introduced into measurements by the stimulation itself.
Here we investigate whether tACS can increase occipital alpha power by stimulating at the second harmonic of the peak individual alpha frequency (IAF). This approach has the advantage that the stimulation artefact is localised at higher harmonics than the frequency of interest which in turn is artefact free.
Our paradigm was based on previous studies where the occipital alpha rhythm was targeted via tACS. Subjects sat in front of a monitor fixating a cross and performed an auditory attention task for a total of 45 minutes. Each participant was randomly assigned to either stimulation group (N=17) or sham group (N=15). The stimulation group received tACS with frequency equal to double the IAF, and a maximum amplitude set below each subject's perceptual and phosphene threshold. Stimulation started 5 minutes after the beginning of the experiment and lasted 20 minutes. The sham group received only 20s of stimulation. tACS electrodes were positioned over Cz and Oz on the 10-20 system. Brain activity was measured throughout the experiment by EEG. Time-frequency analysis of the EEG data showed an increase of alpha power in the stimulation group compared to the sham group, which was localized to the parietal and occipital areas. This increase was not instantaneous after the onset of tACS, but occurred over a longer time scale, becoming most pronounced in the last minutes of stimulation. Furthermore, an alpha power increase was sustained after the offset of tACS.
Consistent with previous studies demonstrating long lasting aftereffects on the alpha rhythm when stimulating at IAF, we were able to produce a similar effect by stimulating at double the IAF, suggesting that the second harmonic of IAF can interact with neural oscillators generating the alpha rhythm. Additionally, because of the absence of artefact in the frequency band of

interest we were able to observe the time course of alpha power increase during stimulation. We believe that this method could potentially be used to better understand the mechanisms underlying the interaction between brain oscillations and tACS, as well as to develop closed-loop stimulation paradigms.

Title: EEG source localization of human alpha rhythms under propofol anesthesia

Authors: ***E. P. STEPHEN**[1], M. S. HÄMÄLÄINEN[3], S. KHAN[3], E. T. PIERCE[4], P. G. HARRELL[4], J. L. WALSH[4], E. N. BROWN[4,2], P. L. PURDON[4];

Abstract: Propofol-induced unconsciousness is characterized by rhythmic electroencephalogram (EEG) activity in the slow (<1 Hz) and alpha (8-12 Hz) frequency bands. Unlike the occipital alpha rhythm present during eyes-closed wakefulness, the propofol alpha rhythm is most prominent in frontal EEG leads. Theoretical modeling studies propose that both occipital and propofol alpha are mediated by thalamocortical loops, and that the observed anteriorization arises from differential effects of propofol on occipital and frontal thalamocortical networks (Ching et al. 2010, Vijayan et al. 2013). While the propofol alpha rhythm is believed to have a cortical source in the frontal lobe, its precise anatomical source remains to be described. In this

study, we use source localization to identify the anatomical sources of the EEG alpha rhythm in humans. In particular, we perform dipole analysis and minimum norm estimates on EEG recordings from 10 healthy volunteers whose scalp EEG patterns were previously reported in Purdon et al. 2013. We find that the propofol alpha rhythm is better described by a distributed model than by a focal source. The alpha rhythm is prominent over a wide region of the frontal lobe, with the largest increases in alpha power occurring over the anterior cingulate gyrus and the dorsal and medial surfaces of the superior frontal gyrus. Using principal angle analysis with the subjects' individual neuroanatomy, we assess the ability of the analysis to distinguish between medial and lateral frontal lobe activity. Our findings provide empirical support for a model of propofol alpha that is distributed over the frontal and anterior cingulate cortices.

Title: Differentiating psychotic disorders with EEG delta and alpha band frequency and the effects of brief high frequency repetitive transcranial magnetic stimulation

Authors: *F. M. HOWELLS, J. HSIEH, H. TEMMINGH, D. J. STEIN;
Univ. of Cape Town, Cape Town, South Africa

Abstract: Diagnostics within the psychotic disorders can appear to be challenging in the clinical setting. It is essential that the optimal medications are prescribed as soon as the initial psychotic episode has subsided as this provides the best prognosis to the individual that presents with a psychotic illness. Further, current treatments - antipsychotics, have been shown to ineffectively manage psychotic symptoms in up to 25% of individuals that meet the criterion for a chronic psychotic illness. We investigate whether a simple electroencephalographic (EEG) system would aid delineation of different clinical psychosis phenotypes, and whether high frequency brief repetitive transcranial stimulation (brTMS) is able to affect change, improvement, in EEG frequency activity. Specifically addressing delta and alpha frequencies as these are often highlighted in the literature to change with presentation of psychosis. In the present study we have applied a simple (6 lead montage: F_3, F_4, C_3, C_4, P3, P_4) EEG to three psychotic disorders: schizophrenia (SZ=28), bipolar I disorder with a significant history of psychosis(BPD=28), and methamphetamine-induced psychosis (MPD=24), as per DSM-IV SCID, and a socio-economic control group (CON=29). We report the data from a 3 minute resting eyes closed condition, before and after brTMS (1000 pulses at 20Hz) over the left and right dorsolateral prefrontal cortex, a total of 2000 pulses at resting motor threshold. SZ and MPD showed increased delta activity, decreased alpha, and increased delta/alpha ratios compared to controls for all 6 electrodes. MPD showed increased delta activity for parietal electrodes, decreased alpha and increased delta/alpha ratio for right hemisphere electrodes compared with BPD. brTMS showed several tendencies to further increase delta activity, decrease alpha, and increase delta/alpha ratios in SZ for left central and parietal electrodes. These data support the use of EEG frequency analysis in the delineation of psychotic disorders specifically SZ and MPD from BPD, when compared with controls. brTMS as applied in this study did not show benefit to EEG frequency activity, in fact it exaggerated the differences, specifically over the left central and parietal cortices. However, our finding of brTMS to effect change in SZ contradicts the notion of reduced plasticity, in that we saw depression in networks with stimulation where we expected to find the contrary, i.e. enhanced alpha activity and reduced delta activity.

Title: Spontaneous cortical gamma oscillation and the auditory evoked steady state response: A pharmacological investigation

Authors: *B. D. HARVEY[1], E. MOROZOVA[1], C. KELLEY[2], M. HAJOS[1,2];
[1]Neurol., Biogen, Cambridge, MA; [2]Yale Sch. of Med., New Haven, CT

Abstract: Neurophysiological signals have been used as translational biomarkers validating functional target engagement for a variety of different drug discovery programs. Among the various neurophysiological measurements employed, auditory evoked steady-state response (ASSR) is one such biomarker that has been considered. This is particularly true for schizophrenia as it is consistently impaired in the disorder (Brenner et al., 2009) with phase locking of ASSR positively correlating with positive symptoms/hallucination. ASSR's are obtained from averaging individual responses to trains of auditory rhythmic stimuli delivered at a constant frequency; in humans the ASSR response is maximal at stimulation frequencies around 40Hz. The present study was aimed at investigating the impact of pharmacological interventions that modulate spontaneous gamma oscillations on ASSR measurements (Spencer, 2012). We tested CP-55940, a CB-1 receptor agonist and CyPPA, a SK2/3 positive allosteric modulator. These two compounds have previously demonstrated effects on broadband gamma oscillations by both increasing and decreasing spectral power respectively. Naïve C57BL/6 mice (n = 7) were chronically implanted with monopolar surface electrodes centered over frontal and parietal cortices. Each mouse was placed into an isolated recording chamber, allowed 15 minutes to acclimate after which local field potential activity (LFP) was monitored both prior-to and following presentation of auditory stimuli (30 and 40Hz click trains). This procedure was performed before and after administration of either vehicle, CyPPA or CP-55940. Spontaneous and evoked LFP data were analyzed using Matlab to calculate both spectral power and inter-trial phase coherence (ITPC). Converse to previously reported data in acute and chronic cannabis users (Skosnik et al., 2015), CP-55940 had no significant effect on the amplitude of ASSR. Similarly, CyPPA produced no significant effects on ASSR evoked power. However, analyses of ITPC showed that CyPPA significantly decreased whereas, CP-55940 significantly increased phase coherence in the frontal cortex only. Our findings indicate that ASSR phase locking but not evoked power is potentially influenced by background cortical gamma oscillations and that this should be considered when developing ASSR as a translational neurophysiological biomarker.

Title: Age-related changes in EEG during isoflurane-induced surgical vs. very deep coma anesthesia

Authors: ***P. J. SOJA**, T. MARIAM, X. DONG, R. TADAVARTY;
The Univ. of British Columbia, Vancouver, BC, Canada

Abstract: In adult rats, the cortical EEG during the surgical plane of isoflurane anesthesia (ISO, 1.0-1.5 %) is characterized predominantly by continuously occurring large-amplitude slow waves. Increasing the concentration of ISO beyond 3.5% results in a shift of EEG activity to burst events followed by suppression (*J. Neurophysiol.* 12:137-160,1949). The number of burst events eventually decrease and disappear to the point at which the EEG consists of randomly occurring single or clusters of fast, large-amplitude, sharp (FLAS) waves. FLAS waves are thought to represent a novel form of brain activity but their functional significance is not known (*Anesth. Analg.*, 79:52-57, 1994; *PLoS One* 8(9), e75257, 2013). Given that rats are commonly used to study the aging brain, the present study was performed to determine if the power in the classical frequency bands during surgical anesthesia (1.0-1.5% ISO) as well as the number of FLAS waves that characterize the EEG during very deep ISO coma (3.5%) are preserved in old age. Adult (4-6 months, n=3) and old (~18 months, n=3) male Sprague-Dawley rats were each initially anesthetized with ISO using an anesthetic chamber. The animal's trachea was intubated and its head mounted in a stereotaxic frame. Cortical EEG (S1) was recorded bilaterally using stainless steel electrodes. The concentration of ISO was adjusted to produce a stable baseline EEG over 30 min consisting of large amplitude slow wave activity. ISO was then maintained for 4 hrs while recording the EEG using CED Spike 2 software. The relative power in δ (1-4Hz), θ (5-8Hz), α (9-12Hz), and β (13-25Hz) bandwidths were analyzed with a customized script. The relative power across all bandwidths were compared using a 2 way ANOVA and Bonferroni post-test with age and time as two factors. Relative power values for δ band were significantly higher in old rats when compared to adults over a 4 hr period of ISO anesthesia whereas relative power in the θ band did not change between adult and old animals. In contrast, relative α and β power reversed between adult and old animals, being greater in adult vs. old animals during ISO.

At 1, 2, 3, and 4 hrs of very deep ISO coma, the average number of FLAS waves that occurred in 2 min epochs in adult animals measured 6, 19, 29, and 21, respectively. In contrast, in old animals, the corresponding average number of FLAS waves measured 2, 2, 2, and 3, respectively. FLAS waves in adults occurred not only as singlets, but doublets and triplets, whereas only single events were observed in old animals. These findings demonstrate distinct differences in EEG activities between adult and old animals during surgical *vs.* very deep coma anesthesia.

Title: Investigations of phase-amplitude coupling and long-range phase synchronization during multisensory working memory maintenance - an MEG study

Authors: *J. DAUME[1], T. GRUBER[2], A. K. ENGEL[1], U. FRIESE[1];
[1]Dept. of Neurophysiol. and Pathophysiology, Univ. Med. Ctr. Hamburg-Eppendorf, Hamburg, Germany; [2]Inst. of Psychology, Osnabrueck Univ., Osnabrueck, Germany

Abstract: Working memory (WM) maintenance has been associated with neuronal oscillatory activity over a broad range of frequencies. Recent work showed that the phases of lower frequencies modulate amplitudes of higher frequencies and this phase-amplitude coupling (PAC) has been suggested to serve as a key mechanism for WM storage. Moreover, long-range phase synchronization within low frequency bands have been linked to WM control processes. Most studies, however, investigated such interactions in a unisensory environment. Here, we aimed at examining how divided resources during multisensory WM affect amplitudes, PAC and phase synchronization of oscillatory activity when compared to unisensory WM processes. We used magnetoencephalography to record neural activity of healthy human participants engaged in an audiovisual delayed-match-to-sample task. In each trial, participants were stimulated twice with a simultaneous presentation of a picture and a sound. Their task was to judge whether stimuli

were the same or different within the modalities. To this end, visual and auditory stimuli were always modified independently from each other. In one condition, participants had to focus on the visual stimulus only, while in the other, responses for both the visual and the auditory stimuli were required. This setup allowed us to compare unisensory WM processes against those where resources were distributed across sensory systems. As expected, in both conditions sensory regions showed elevated beta and gamma as well as decreased alpha power throughout the delay period. Frontal areas predominantly exhibited increased theta power. Differences in power between the conditions were apparent in frontal regions, where multisensory WM led to more theta power. Further, a cluster of occipital sensors showed stronger alpha-gamma PAC during periods of distributed resources. Source estimates located this effect in right extrastriate area V3. Comparing imaginary coherence between the conditions within the alpha band revealed weaker long-range phase synchronization between right and left V3 during audiovisual WM. Our results provide insights into interactions of neuronal oscillations during multisensory WM maintenance. They suggest that stronger alpha-gamma PAC and weaker alpha-band phase coupling within the visual system may be a neural correlate of increased task demands when resources are distributed between sensory systems that are engaged in WM maintenance.

Title: Dopaminergic medication restores abnormal theta-band neural synchronies during a working memory task in patients with restless legs syndrome

Authors: ***K. CHA**[1], J. CHOI[1], P. SEO[1], B. LEE[2], K.-Y. JUNG[2], K. KIM[1];
[1]Dept. of Biomed. Engin., Yonsei Univ., Wonju City, Korea, Republic of; [2]Dept. of Neurology, Seoul Natl. Univ. Med. Ctr., Seoul, Korea, Republic of

Abstract: Restless legs syndrome (RLS) is a sensorimotor neurological disorder which is characterized by an irresistible urge to move one's legs. Dopaminergic agonists play a role in improving cognitive function in RLS patients, but its neural mechanism remains unknown. In

this study, to identify the electrophysiological evidences of the effect of dopaminergic medication on cognitive function in RLS patients, we investigated interregional neural synchronies during a working memory task.13 normal controls and 13 drug naïve RLS patients participated in the study. Two event-related potential (ERP) recordings were performed; the first was just before giving the first dose of pramipexole (baseline condition) and the second was at 12 - 16 weeks after commencement of pramipexole administration (follow-up condition). Subjects performed a Sternberg working memory task. At encoding phase, a series of digit number was presented after visual orienting cue sign. After 2-s maintenance interval, a probe item was shown at retrieval phase. Subjects were required to press a button if the probe corresponded to one of the number shown in the encoding phase. During the task, 19 channel electroencephalograms (EEGs) were recorded. We analyzed the event-related interregional phase synchrony in theta-band (TBPS) during retrieval phase. The spatial pattern of TBPS was quantitatively analyzed using graph theoretical measures, including clustering coefficient (C) and characteristic path length (L). At 400-700 ms after the prove onset, considerable increment of TBPS was observed mainly between anterior and posterior regions for all subjects. At this period, the anterior-posterior TBPS for RLS patients in baseline condition remarkably weaker compared to normal control, but recovered after the medication. RLS patients in baseline condition showed significantly reduced C and increased L compared to normal controls. However, this alteration for RLS patients was significantly recovered to the normal level after the medication. In sum, we observed significant alterations of interregional neural synchronies and inefficient brain networks for RLS patients, which may underlie the deficit of working memory function associated with RLS. Also, theses abnormalities were restored after dopaminergic medication. Our findings imply that dopamine plays a major role in the cause and recovery of cognitive deficit in RLS patients.

Title: High frequency oscillations evoked by tones in auditory cortex

Authors: *Y. KAJIKAWA[1,2], C. E. SCHROEDER[1,2];
[1]Nathan Kline Inst., Orangeburg, NY; [2]Neurolog. Surgery, Columbia Univ., New York, NY

Abstract: Electrocorticographic (ECoG), signals in the 70-200 Hz range, variously called broad band "high frequency" (HF) or "high-gamma" (HG), have a broadband power distribution that is generally believed to reflect massed multiunit neuronal firing in neuron populations near the recording electrode. It is often assumed that ECoG signals in the this range do not contain oscillatory signals, though earlier intracortical recordings in monkeys and scalp EEG recordings in humans report that high frequency oscillations (100-200 Hz) can be evoked by intense, rapid onset auditory and visual stimuli.
We recorded field potential (FP) and multiunit activity (MUA) responses to tones in the macaque auditory cortex, using linear-array, multielectrodes, and addressed the laminar pattern of HG activity. FPs and MUA in auditory cortex responded to pure tones (100 ms duration, 60dB) at an average onset latency of about 10 msec. In subsets of cortical sites, the FP onset response to the local best frequency tone was followed by a transient rise in the amplitude of HG activity, whose instantaneous frequency changed dynamically from about 200 Hz to 80 Hz over a 40-70 ms period, beginning at 30 ms from tone onset. Current source density (CSD) analysis of the FP profile revealed that the laminar extent and distribution of this HF activity varied across recording penetration sites with a bias toward the granular and supragranular layers. CSD analysis also showed that the neuronal generators of the HF response are oscillating current source/sink configurations that clearly replicate the dynamic shift from ~200-80 Hz from 30-100 ms poststimulus, observed in the FPs. These results indicate that tone-evoked HG activity in auditory cortex is generated by a spatially delimited, current dipole oscillating at the HG frequency. Dependence of the HG amplitude on the tone frequency showed spectral tuning of HG was similar to concomitant MUA. However, no apparent relationship between HG phase and MUA was observed.

Abstract: Rapid-eye movement (REM) sleep behavior disorder (RBD) is a sleep disorder characterized by dream enactment behavior and the loss of muscle atonia during REM sleep. In this study, we compared functional cortical networks during REM sleep between healthy controls and RBD patients, in order to investigate abnormal changes of neural synchrony in RBD patients. Drug-naïve idiopathic RBD patients and healthy controls were participated in the experiment. 21 channel electroencephalograms (EEGs) were recorded during one overnight sleep. Artifact-free 30s epochs in REM sleep stage were analyzed. In order to examine the differences in local and global neural synchronies between two groups, time-varying spectral power and inter-regional phase synchronizations (PS) were investigated. The spatial characteristics of the pattern of PS were quantified by graph theoretical measures. Significantly increased power and centroparietal connection were observed in delta-band for RBD patients compared to normal controls. In RBD patients, the number of connections at delta-band were anti-correlated with Korean version of the sniffin' sticks test (KVSS) score, which is known as a good index of the severity of neurodegenerative disease. Significantly reduced clustering coefficient and increased characteristic path length were observed for the RBD patients compared to normal controls. The small-worldness propensity, which represents the network efficiency, was significantly reduced for the RBD patients compared to normal controls in delta- and alpha-bands. The increments of delta- and theta-bands power during REM sleep were known as EEG slowing activity, which reflects neurodegeneration in the neurological patients. The abnormally increased neural synchronies in our results can be understood as reflecting the neurodegenerative process associated with RBD. The alteration in the functional cortical network in delta and alpha bands reflects loss of the small-world network characteristics in the RBD patients. The abnormal subband power and functional connectivity may serve as EEG-based neuromarkers for the RBD.

Title: Stability of timing and connectivity in functional networks of the human cortex

Authors: *J. CHAPETON, S. K. INATI, K. A. ZAGHLOUL;
NINDS, NIH, Bethesda, MD

Abstract: Despite many advances in the study of large-scale functional networks, the question of timing, stability, and direction of communication between cortical regions has not been fully addressed. We hypothesized that if two brain regions are communicating, the activity of one should predict the activity of the other with a consistent time delay. Although such predictive relationships have been identified between neurons using measures of effective connectivity, it is not known whether similar relationships exist between cortical regions. We examine this question here using resting-state intracranial EEG captured from nine human participants with medically refractory epilepsy. We used a coupling measure based on time-lagged mutual information to identify effective connections between brain regions that exhibit a statistically significant increase in average mutual information at a consistent time delay. We constructed functional networks based on these connections and found that individual connections and overall network topology were stable over minutes, hours, and days. Notably, the time delays associated with these connections were also highly preserved over multiple time scales, suggesting the presence of stable functional networks in the human brain. We identified individual brain areas that exhibited stronger homogeneity in their connections across data blocks; there was no clear anatomic distribution of these stable nodes. However, we found that a node's homogeneity across time was strongly correlated with its degree and clustering coefficient, suggesting that network stability is in large part mediated by highly connected nodes and their partners. We characterized the spatial properties of information flow through these functional networks, and found a preferred posterior to anterior temporal lobe direction, consistent across all participants. Our results demonstrate that cortical regions exhibit functional relationships with well-defined and stable timing, and suggest that connectivity and time delays between brain regions are highly consistent across multiple time scales.

Title: EEG connectivity analysis for healthy adults under anesthesia

Authors: *J. CHOI[1], S. AHN[1], H. CHO[1], M. KWON[1], S. LEE[1], S. JANG[1], B.-M. CHOI[2], G.-J. NOH[2,3], S. JUN[1];

Abstract: Electroencephalography (EEG) is commonly used to measure the depth of anesthesia. Clinical signs and EEG patterns during general anesthesia is well understood. There exist many reports about connectivity diminishment between the frontal and parietal areas by loss of consciousness. Propofol is a typical GABAergic anesthetics which disrupts the fronto-parietal network. In this study, we tested the hypothesis that propofol would inhibit cortical connectivity in frontoparietal networks using MATLAB connectivity toolbox "HERMES".
Healthy subjects (n=15) were recruited for induction of anesthesia with intravenous propofol (12mg/kg/h); EEG data with 6 channels (Fp1, Fp2, F3, F4, P3, and P4) were acquired. For every subject, resting state EEG data (as a baseline) were acquired for about 5 minutes. The anesthetic was administrated during one hour. EEG data were collected during administration and for 60 minutes after the end of administration. EEG data of each subject were segregated into three states of consciousness (Baseline (resting), Loss of Consciousness (LOC), and Recovery) We measured correlation (COR), coherence (COH), imaginary part of coherence (iCOH), and phase-locking value (PLV) for connectivity analysis between frontal (4 channels) and parietal (2 channels) areas.
By the administration of propofol, the fronto-parietal connectivity was significantly ($p < 0.01$) inhibited during LOC. Average COR decreased from 0.64 to 0.49, COH also diminished from 0.41 to 0.25. iCOH was significantly inhibited since iCOH value of unconscious state was quite lower than that of baseline state. PLV between baseline and unconscious state also showed significant difference, but was relatively inferior to other methods. These results were tabulated in Table 1. Connectivity difference between baseline and recovery states also showed significance for all three measures. However, PLV between LOC and recovery states was not significant ($p = 0.074 > 0.01$).
Four EEG connectivity measures for healthy adults under general anesthesia process were

compared. Every measure detected the disruption of frontal-parietal communication, despite PLV yielded relatively weak connectivity difference between consciousness states.

Abstract: Investigation of an inter-brain synchronization during social interaction has gained significant attention. One EEG study attempted to address inter-brain coordination when two subjects were engaged in verbal communication, and oscillatory modulations in the theta and alpha bands were reported. However, there are only few studies on verbal interaction and its significant inter-brain connections are still under investigation. In this work, therefore, we performed reciprocal live verbal interactions between humans, and collected EEG data to investigate intra- and inter-brain functional connections. Nine males and one female (five-pair) participated in live verbal interaction. Every randomly paired subjects performed the experiments in two different magnetically and electrically shielded rooms, one room for each. Distance between two shielded rooms is about 100 miles. Nineteen channels EEG system was used. Subjects were instructed to interact only verbally with their partner by counting the number from 1 to time limit. For the first 5 seconds, instruction was displayed in the screen and subject prepared to do given task with yellow characters and black background. After this instruction period, a task period was begun with black blank screen during 30 seconds. There are two tasks in this task period. First task is interaction task (INT) which each subject performed turn-taking number counting from 1 to time limit (30 seconds). Second task is speaking task (SPE) which each subject counts the numbers from 1 to time limit for oneself. After task period, break instruction was displayed for 5 seconds. Each subject stops the counting and prepares for next trial in this period. Instruction, task and break period are 1 trial and duration is 40 seconds. It consisted of 12 trials per run and 5 runs were obtained. For connectivity analysis, we adopted weighted phase lag index to minimize the effect of volume conduction. With a thousand surrogated data, the statistical significance of functional connectivity was estimated. As a result, a strong functional intra- and inter-connections were observed between left temporal and right centro-parietal lobes in EEG alpha band (8-12Hz) during INT condition compared to SPE. Right centro-parietal lobe plays an important role in social interaction and it is called phi-complex as a neuromarker of human social coordination. In addition, left temporal lobe (left superior temporal gyrus) is in charge of auditory perception and manipulation as following ventral stream of the brain. These neurophysiological evidences support our findings which is significant functional connections in two specific brain regions.

Title: 0.0002 Hz fluctuations in human intracranial DC recordings

Authors: *G. PIANTONI[1,2], E. S. ROSENTHAL[1,2], E. HALGREN[3], S. S. CASH[1,2];
[1]Massachusetts Gen. Hosp., Boston, MA; [2]Harvard Med. Sch., Boston, MA; [3]UCSD, La Jolla, CA

Abstract: Neural activity is organized in rhythms at multiple temporal scales, from the circadian to the ultra-fast oscillations. While the electroencephalography commonly records oscillations in the range of 0.1 to 100 Hz, the presence of very slow fluctuations has been difficult to assess due to the widespread use of hard-pass filters.
In this study, recordings were acquired with a full-band amplifier in intracranial electrodes implanted for clinical mapping of the epileptogenic zone in patients with intractable epilepsy, continuously over the course of a few days. We measured the difference in DC potentials between neighboring channels belonging to depth electrodes in prefrontal and temporal cortices. This setup prevents the potential confound that our findings are affected by changes in skin conductance that have limited previous DC studies.
We show, for the first time to our knowledge, the existence of fluctuations with a period of 1-2 hours in the human brain. The ultra-slow oscillations were of an amplitude in the order of mV, which is considerably larger than previously reported brain rhythms, and were present during both wakefulness and sleep. Crucially, the cycle of the ultra-slow fluctuations was correlated with the sleep cycle, especially at the beginning of the night. This observation was confirmed by the cross-frequency coupling which was present exclusively during sleep: the phase of the ultra-slow fluctuations entrained the power in the slow wave band (~1 Hz).
In conclusion, we show that the human brain generates ultra-slow fluctuations of very large amplitude in the order of 1-2 hours. These ultra-slow fluctuations synchronize the sleep cycle and their phase might indicate the propensity to fall asleep. We speculate that these fluctuations represent a potential correlate of the Basic Rest-Activity Cycle (BRAC), a putative rhythm that organizes the level of vigilance during wakefulness and the sleep cycle during sleep.

Title: Neural network dynamics during recovery from isoflurane as revealed by electroencephalogram in young and old rats

Authors: *B. F. COUGHLIN[1], S. S. CASH[2,3], E. Y. KIMCHI[2,3];
[2]Dept. of Neurol., [1]Massachusetts Gen. Hosp., Boston, MA; [3]Harvard Med. Sch., Boston, MA

Abstract: General anesthesia is ubiquitous in invasive surgical procedures. However, despite widespread use of anesthesia, the neural network dynamics of the anesthetized state remain unclear, particularly during recovery. Additionally, both older patients and older animal subjects recover more slowly from anesthesia, as defined by behavioral measures. The global oscillatory dynamics during recovery from anesthesia have neither been comprehensively described nor extensively compared between older and younger subjects. To characterize the neurophysiologic signatures of recovery from anesthesia and compare them between older and younger subjects, we recorded EEG and EMG from young (aged 2-4 months, n=15) and old (aged 22-24 months, n=13) rats during and following 2% isoflurane anesthesia. EEG and EMG recordings during two hours of isoflurane anesthesia revealed burst-suppression in all subjects. Recordings were then continued after the conclusion of isoflurane anesthesia through behavioral recovery, as defined by the return of righting reflex (RORR). As there are currently no well-defined electrographic stages of recovery from anesthesia, we first qualitatively characterized EEG and EMG changes during recovery. Spectral representations of EEG and EMG recordings revealed a consistent progression of several features or states during the recovery from isoflurane anesthesia, including transitions from broadband activity following burst suppression to a combination of delta, slow theta, and beta band activity. Correlation analyses were performed to determine relationships between features. Interestingly, younger animals appeared to remain in post-anesthesia burst suppression longer than older animals, but ultimately recovered their righting reflex more quickly. Higher frequency EEG and EMG activity appeared to predict the return of righting reflex in all subjects, but with particular distinctions in young and old subjects. While quantitative analyses are ongoing, it is our hope that the identified neurophysiologic states can serve as markers of recovery and can begin to lay the groundwork for a more-complete picture of the course of anesthetic recovery and the neural networks involved.

Title: Characterization of networks for rule processing in human stereoEEG data using consensus-based partial coherence

Authors: ***M. TER WAL**[1,2], P. CARDELLICCHIO[3], G. A. ORBAN[3], P. H. TIESINGA[1,2]; [1]Neuroinformatics, Radboud Univ., Nijmegen, Netherlands; [2]Donders Inst., Nijmegen, Netherlands; [3]Dept. of Neurosci., Univ. of Parma, Parma, Italy

Abstract: The demands for sensory processing are dependent on context. To study context related changes in visual processing, we set up a task in which the visual stimulus was identical throughout the experiment, while the desired output changed between two rules: color and orientation. Throughout the experiment we recorded local field potential signals in epilepsy patients that were admitted for presurgery evaluation and had cylindrical stereo-electroencephalography (sEEG) electrodes implanted across frontal brain regions in one or both hemispheres.

One approach to characterize functional networks in sEEG is to compute pair-wise coherence between channels, an undirected measure of spectral covariance, which is computationally efficient. However, pair-wise coherence is confounded by shared inputs to the studied pair: a high coherence may be obtained, even in the absence of an underlying connection. The coherence can be corrected for shared inputs by conditioning on the data from all other simultaneously recorded channels, yielding the so called partial coherence [1]. Calculating the partial coherence involves inverting the n-by-n cross-spectrum matrix, where n is the number of recorded channels. Partial coherence can perform well for datasets with a few channels, but for sEEG data, with its high channel count, the matrix becomes ill-conditioned, preventing accurate estimation of its inverse.

Here, we present a solution to this conditioning problem. Instead of conditioning on the full dataset, channels are pooled into a small number of groups and conditioning is performed on the set of group-averages. By repeating this procedure for different random groupings of channels, a reliable consensus is reached for the partial coherence of a pair. We first validated this approach

for a range of conditions in model data. The modeling results confirmed that partial coherence removed shared inputs from the network characterization, while maintaining direct connections. Subsequently, we demonstrated that consensus-based partial coherence can be used to identify networks in sEEG data recorded in epilepsy patients. Here too, it reduced the identified networks for rule processing, in a time and frequency resolved way. Taken together, this new methodology allows for assessing functional brain networks in large data sets.

Title: Cross-frequency coupling: the theoretical framework.

Authors: *G. CISOTTO;
Univ. of Padua, Padova, Italy

Abstract: Increasing attention is being given to quantify the so-called cross-frequency coupling (CFC), that is the relationship between brain activities at different frequencies. Particularly, recent empirical evidence shown that neuronal activity at low frequency, e.g. theta band, modulates with its phase changes the magnitude of neuronal activity at higher frequency, e.g. gamma band, in the same area or in another one, functionally connected with the first one. Several methods have been employed to quantify this phenomenon in different kinds of electrophysiological signals. Unfortunately, several parameters had to be a priori determined: the frequency and the bandwidth of the two components interacting in the CFC, above all. Their selection has been most often data-driven. Moreover, the output of such methods is usually represented by an index that is supposed to quantify the strength of the coupling. However, no realistic range for it exists, unless a very conservative [0,1] range that has already been shown to be overestimated, being the most common empirical values in the order of 0.001. This contribution aims at translating the well-known theoretical framework about signal modulation from its original field of communication engineering to the study of CFC. Thanks to it, it was possible to limit the range of the most important parameters in order to ensure a proper coupling.

Besides, a common driver for the two signals - a third one at a much lower frequency - could be also extracted, providing support for the hypothesis of a common generator of the CFC mechanism. A simulator for the CFC was designed as the parallel modulation in phase (PM) of a low frequency signal xL(t) and in amplitude (AM) of a high frequency one, xH(t). Their coupling was given by a third signal a(t) that simultaneously drove the phase changes of xL(t) and the amplitude variations of xH(t). Using this controlled environment, it could be possible to test the variation of CFC strength produced by changing the different parameters of interest. Optimal demodulator for decoding CFC from a typical CFC signal was designed as well. The strength of CFC was computed by the Pearson's correlation coefficient ρ between the two signals obtained at the demodulator output from the low and high frequency components, respectively. Thus, the optimal choice of parameters could be identified as the combination at which a maximum ρ is achieved. This contribution provides a platform (i) to simulate an expected strength of CFC, (ii) to test the effectiveness of a specific standard method of quantification of CFC and (iii) to optimally demodulate both PM (xL(t)) and AM (xH(t)) components to check if the common generator a(t) exists.

Title: Site-dependent effects of optogenetic stimulation in thalamic reticular nucleus on cortical states

Authors: *V. VISOCKIS[1], S. SAKATA[1], B. MORRIS[2], J. PRATT[1];
[1]Strathclyde Univ., Glasgow, United Kingdom; [2]Glasgow Univ., Glasgow, United Kingdom

Abstract: The corticothalamic loop has long been implicated in the range of neuropsychiatric diseases. The thalamic reticular nucleus (TRN), a part of the corticothalamic loop, plays a key role in selective attention and sleep spindles. Furthermore, sleep spindles are reduced in amplitude and duration in schizophrenia patients, implying clinical relevance of TRN functions. However, while the TRN is topographically organized, it still remains unclear whether and how the TRN consists of functionally distinct sub-regions. Combining optogenetic and

electrophysiological approaches in mice, we investigated changes in sleep spindles and EEG oscillations caused by optogenetic stimulations in different parts of the TRN. Archaerhodopsin (Arch), a light sensitive proton pump, was expressed specifically in either an anterior or posterior part of the TRN in parvalbumin (PV)-Cre mice using adeno-associated viral vectors. We found restricted expression patterns of Arch in PV-positive neurons of the TRN depending on injection sites. Effects of optical stimulation on cortical EEGs were assessed by delivering green light through chronically implanted optic fibers over up to 1 min periods in freely behaving animals. Tonic stimulations during awake states did not produce any significant change in EEGs whereas stimulations during sleep modulated delta power and the number of sleep spindles. Together these data support the notion that activity in the TRN may have different impacts on the modulation of cortical states in a site-dependent manner.

Title: Contrasting properties of hippocampal dentate gyrus and CA1 principal cells

Authors: ***S. A. PARK**[1], D. A. COULTER[1,2,3];
[1]Neurol., [2]Pediatrics, Children's Hosp. of Philadelphia, Philadelphia, PA; [3]Neurosci., Univ. of Pennsylvania, Philadelphia, PA

Abstract: The hippocampus is known to be involved in spatial learning and navigation, where each region behaves differently and performs distinct functions. In vivo, dentate granule cells (DGCs) are less responsive to afferent stimulation compared to CA1 pyramidal cells (CA1 PCs), which we also demonstrated in vitro by imaging the expression of the fluorescent, activity dependent label CaMPARI in DGCs and CA1 PCs in horizontal hippocampal slices in response to afferent stimulation. Using current-clamp, we explored intrinsic and synaptic properties that could underlie the variable responsiveness of the two cell types. We identified several intrinsic properties that could contribute to DGCs being less excitable than CA1 PCs. DGCs had a larger input resistance, more hyperpolarized membrane potential, and a higher voltage threshold for generating the 1st action potential compared to CA1 PCs. However, DGCs also had lower membrane capacitance and less dendritic branching. We also recorded aggregate synaptic

responses composed of EPSPs and IPSPs in current-clamp mode in response to a threshold afferent stimuli, and calculated the response amplitude at times corresponding to peak activation. DGCs were harder to excite as well as inhibit synaptically compared to CA1 PCs. The peak DGC EPSP (3.3 nS) and IPSP (3.2 nS) conductances were both smaller compared to CA1 EPSP (8.2 nS) and IPSP (6.8 nS), respectively, indicating lower levels of activation of DGCs by threshold stimuli. Additionally, our data show that in CA1 PCs, IPSPs follow EPSPs and are sustained for at least 100 ms post-stim, whereas the majority of DGC EPSPs reach peak earlier than CA1 EPSPs and are smaller in magnitude, with no apparent early or delayed IPSP, which suggests that the DGC response was an aggregate, extensively overlapping EPSP/IPSP, which dampened excitation. Overall, our data show DGCs are harder to excite and temporal overlap in synaptic inputs may be a primary mechanism determining DGCs' reduced synaptic excitability compared to CA1 PCs. Continued investigation of synaptic connections and microcircuit properties in cells with identified aggregate responses may further clarify how each hippocampal cell type processes synaptic input to generate their regionally characteristic behavior.

Title: Impairment of homeostatic synaptic scaling in epileptic immature brain

Authors: *H. SUN, D. TALOS, F. E. JENSEN;
Dept. of Neurol., Univ. of Pennsylvania, Philadelphia, PA

Abstract: Synaptic scaling stabilizes network excitability by adjusting synaptic strength in response to chronic global changes in neuronal firing. Synaptic scaling is most robust in neurons during early development, and our previous study has shown a PLK2-mediated homeostatic compensation following early-life seizures. However, this homeostatic downregulation of

excitability was incomplete and negatively regulated by co-activation of mTOR pathway. Here, we aimed to determine the capability of neurons in epileptic immature brain to generate homeostatic synaptic scaling. Early-life Seizures (HS) were induced by acute global hypoxia in P10 rats. *Ex vivo* slices were maintained *in vitro* for 48-72h using an acute culture procedure. Whole-cell clamp recordings were made in cortical pyramidal neurons of somatosensory cortex from post-HS 48h rats and littermate controls. Human epilepsy biopsy tissues were collected following surgical resection for medically intractable epilepsy. We found that at 48-72hrs post-HS, the spontaneous firing rate was significantly higher in neurons from post-HS rats (0.35±0.036 Hz, n=9) compared to normoxic controls (0.11±0.026, n=7, $p<0.001$). Chronic activity blockade by 0.001mM TTX for 24-48h induced significant increases in amplitude and frequency of AMPAR mEPSCs in neurons from both HS rats (Amplitude: 12.3±0.5pA vs 16.6±0.8pA, n=6-8, $p<0.05$; Frequency: 100±15.2% vs 151.2±18.2%, n=6-8, p=0.0507) and normoxic controls (Amplitude: 10.3±0.7pA vs 12.8±0.6pA, n=7-8, $p<0.05$; Frequency: 100±13.2% vs 161.2±21.4%, n=7-8, $p<0.05$) with no changes in AMPAR mEPSC rising and decay time (all $p>0.05$, n=7-8). However, the decreases in synaptic strength in response to elevated synaptic activity by application of 0.1μM Picrotoxin 24-48h as identified in controls (Amplitude: 8.26±0.59pA, n=7, $p<0.05$; Frequency: 83.59±15.67%, n=7, p=0.433) was occluded in neurons from post-HS rats (Amplitude: 13.29±0.49pA, n=8, p=0.179; Frequency: 93.57±20.95%, n=8, p=0.807). In human epilepsy biopsy cortical slices, synaptic scaling down in response to 48h elevated synaptic activity by application of Picrotoxin was abolished (AMPAR mEPSC amplitude: 9.4±0.3pA vs 9.7±0.4pA, n=6-8, $p>0.05$; Frequency: 100±10.2% vs 163.1±13.2%, n=6-8, $p<0.05$), while scaling up in response to 48h synaptic activity blockade by TTX was remained (AMPAR mEPSC amplitude: 11.8±0.6pA, $p<0.05$; Frequency: 112.6±12.9%, $p>0.05$, n=7). These data suggest an impaired synaptic scaling down in cortical neurons in epileptic immature brain, which may, at least in part, contribute to neonatal seizure-induced long-term neuronal hyperexcitability and epileptogenesis.

[2]Univ. of Illinois at Urbana Champaign, Neurosci. Program, Urbana, IL

Abstract: Kv7/KCNQ channels composed of KCNQ2 and KCNQ3 subunits are voltage-gated potassium channels, underlying the neuronal M-current (I_{KM}), that potently limits repetitive and burst firing of action potentials in neurons. Consistent with their ability to inhibit excitability, they are preferentially enriched at the plasma membrane of the axon initial segment (AIS) and axon. Mutations in KCNQ2 have been associated with a wide spectrum of early-onset epileptic disorders ranging from benign familial neonatal seizures (BFNCs), an autosomal-dominant epilepsy of newborns, to severe epileptic encephalopathies (EEs). Some EE mutations are found in the calmodulin (CaM)-binding regions of intracellular carboxy-terminal tail of KCNQ2 (R333W, M518V, R532W and K526N). We found that these EE mutations on the KCNQ2 C-terminal tail variably disrupted CaM binding to KCNQ2. To test the extent to which EE mutations disrupt voltage-dependent outward K^+ current through KCNQ channels, we performed whole-cell voltage clamp recording in CHOhm1 cells. We found that that expression of R333W and M518V mutants showed much smaller voltage-dependent outward K^+ current and current density than expression of wild-type KCNQ2. Interestingly, KCNQ2-K526N mutant channels opened at less depolarizing potential than the wild-type KCNQ2 channels. Our results indicate that the EE mutations reduce KCNQ current by disrupting KCNQ2 interaction with CaM binding. These current reductions in combination with decreased axonal surface expression and protein stability of KCNQ channels (Cavaretta et al., poster) would cause severe defects in the ability of KCNQ channels to inhibit neuronal hyperexcitability, ultimately leading to epilepsy.

Title: Low KCC2 expression in reticular thalamic neurons is sufficient to regulate network activity

Authors: *P. M. KLEIN, M. E. HARPER, H. M. MCKOWN, M. P. BEENHAKKER;
Univ. of Virginia, Charlottesville, VA

Abstract: Large-scale thalamocortical network oscillations underlie seizures associated with absence epilepsy. While GABAergic signaling among reticular thalamic (RT) neurons likely suppresses hypersynchronous thalamic activity, it remains unresolved whether this desynchronizing mechanism occurs through excitatory or inhibitory transmission. Inhibitory GABAergic signaling has long been thought to depend on Cl^- extrusion by chloride cotransporter proteins, including KCC2. Yet previous studies report virtually nonexistent KCC2 expression among RT neurons, thus supporting a hypothesis that GABAergic signaling exerts a depolarizing effect. However, this conflicts with both the existing thalamocortical circuit models and our own finding that GABA inhibits RT neurons. Therefore, we aim to determine the diverse mechanisms that regulate thalamic Cl^- homeostasis and GABAergic signaling. While our immunohistochemical staining from P10-40 Sprague Dawley rats indicates KCC2 levels are indeed significantly reduced in RT relative to other thalamic regions (P10: 70±3.3%, P20: 68±2.7%, P40: 62±4.1%, $p<0.001$ and $n=4$, normalized to ventrobasal thalamus expression), RT still expresses moderate, functionally relevant KCC2 levels. We then measured the GABA reversal potential (E_{GABA}) of RT neurons and show that it supports inhibitory GABAergic signaling (E_{GABA}: -62±3.1 mV, $n=13$). The KCC2 antagonist VU-0463271 depolarizes the E_{GABA} of RT (ΔE_{GABA}: +16±5.4 mV, $p=0.003$, $n=5$), confirming its functional relevance.Impermeant anion distribution, both within and surrounding neuronal somata, are also reported to regulate intracellular Cl^- concentrations. We have determined that sulfated proteoglycans, components of the extracellular matrix and a major source of extracellular impermeant anions, become significantly upregulated in RT by P15 (P10: 113±6.4% $p=0.064$, P15: 132±5.1% $p<0.001$, P40: 172±12.3% $p<0.001$, $n=4$ for all). These extracellular impermeant anions appear to contribute to Cl^- homeostasis in RT.As we have identified a critical role of KCC2 in regulating GABAergic signaling among RT neurons, we sought to determine how this mechanism regulates absence seizures. Alteration of KCC2 activity in the thalamus of WAG/Rij rats, through targeted microdialysis infusions, has allowed us to observe the role of this important Cl^- cotransporter on spontaneously occurring absence seizures. Similar changes in network activity of thalamic slices was observed with functional calcium imaging. By clarifying the mechanisms that regulate thalamic oscillatory activity, we hope to provide new targets for treating absence epilepsy.

Title: Cardiac and respiratory consequences of repeated epileptic seizures in rat

Authors: D. PEDERSON[1], A. ASHBY-LUMSDEN[3], P. P. IRAZOQUI[2], *J. G. JEFFERYS[4]; [1]Biomed. Engin., [2]Weldon Sch. of Biomed. Engin., Purdue, West Lafayette, IN; [3]Pharmacol., [4]Univ. of Oxford, Oxford, United Kingdom

Abstract: Sudden death in epilepsy (SUDEP) is a significant and devastating risk in some kinds of epilepsy. The most likely explanations are respiratory or cardiac failure during or following a seizure. To determine the impact of recurrent seizures on cardiac and respiratory function we induced temporal lobe epileptic foci by injecting tetanus toxin (5-10 ng in 400 - 1000 nl) into rat hippocampus. Spontaneous seizures started a few days later, each lasting <2 min. Status epilepticus did not occur at any stage. We implanted wireless telemetry devices (either a subcutaneous Bionode developed and manufactured at Purdue, or an intra-abdominal Millar TR50BB). Leads were tunnelled subcutaneously to ECG and ECoG electrodes and, in the case of the Bionode, to a thermocouple implanted in the nasal passage. Telemetry and video recordings were made for <6 weeks after injection, and in some cases for 1-2 weeks before injection. Heartrate increased during nearly all seizures and remained high for minutes to tens of minutes afterwards. This postictal tachycardia could occur when the rat was completely inactive and was exacerbated by postictal physical activity. Arrhythmias were common during secondarily generalised seizures and included missed beats, asystoles, premature ventricular depolarizations, torsades and fibrillation. Progressive changes occurred over the duration of the epileptic syndrome. Interictal QT interval, measured for 5-s epochs where heartrate was 350 per min, progressively lengthened from a baseline of ~60 ms, by ~15 ms after >50 seizures. Prolonged QT most likely reflects changes in cardiac ion channels and may increase the risk of arrhythmia. Respiration was affected by epileptiform activity, including interruptions of respiratory rhythm after ECoG spikes and hyperventilation >120 per min during postictal immobility. These seizure-related cardiac and respiratory dysfunctions should be considered as potential risk factors for SUDEP.

Title: Elevated gonadotropin-releasing hormone neuron firing activity in a female mouse model of temporal lobe epilepsy

Authors: J. LI[1], V. A. ABEJUELA[2], J. KIM[2], J. B. LAMANO[2], N. J. KLEIN[2], M. A. GHANE[2], D. J. REYNISH[2], *C. A. CHRISTIAN[3,1,4,2];

Abstract: Reproductive dysfunction is a major co-morbidity of temporal lobe epilepsy for both men and women. A large degree of reproductive dysfunction appears to arise from seizure activity, but the mechanisms linking temporal lobe seizures to the control of reproduction are unclear. In order to assess the neural control of reproduction in the epileptic brain, we used a mouse model of temporal lobe epilepsy in which the convulsant kainic acid (KA) is stereotaxically injected into the hippocampal CA1 region. Control mice were injected with saline vehicle. First, we assessed the reproductive function of female C57BL/6J mice by daily vaginal smears for up to 2 months after KA/saline injection (saline n=10 mice; KA n=12). The majority of KA-treated mice developed disrupted estrous cycles within 2 months after injection. The estrous cycle irregularity was characterized by increased time spent in diestrus (saline 38.01%; KA 50.77%; p=0.04) and longer cycle length (saline 5.00 ± 0.15 d; KA 9.54 ± 1.62 d; p=0.03). We hypothesized that this disruption to estrous cyclicity arises, at least in part, via disrupted function of the hypothalamic gonadotropin-releasing hormone (GnRH) neurons, which form the final common pathway in the central control of reproduction. Therefore, we applied this epilepsy model to mice expressing the red fluorescent protein tdTomato in GnRH neurons. The spontaneous firing activity of GnRH neurons was recorded in acute brain slices by targeted extracellular loose patch recordings at 2 months after injection. GnRH neurons from KA-treated mice with irregular cycles showed a significantly higher average firing rate than control (p= 0.03) (saline 0.31 $\pm$ 0.06 Hz n=19 cells from 9 mice; KA/irregular 2.07 $\pm$ 1.11 Hz n=18 cells from 7 mice). Importantly, the mean firing rate of GnRH neurons from KA-treated mice that maintained regular cycles was not changed (KA/regular n=11 cells from 5 mice; p>0.1 compared to saline control). This suggests that the elevated GnRH neuron activity and estrous cycle disruption may be correlated. In male mice, by contrast, KA treatment did not significantly affect GnRH neuron firing rate (saline n=12 cells from 8 mice; KA n=15 cells from 8 mice; p>0.5),

indicating a potential sex difference in the response of the GnRH network to intrahippocampal KA injection. This is the first direct demonstration of GnRH neuron dysfunction associated with epilepsy. In summary, the intrahippocampal kainic acid mouse model of temporal lobe epilepsy appears appropriate for studying epilepsy-associated female reproductive dysfunction, which may be correlated with elevated GnRH neuron activity.

Title: Resting state glutamatergic activity revealed two independent epileptogenic networks in mesial temporal lobe epilepsy

Authors: ***J. BANERJEE**[1], A. DIXIT[1], V. VISHWANATHAN[1,2], A. SRIVASTAVA[3], B. RAMANUJAM[4], M. TRIPATHI[4], P. SARAT CHANDRA[3];

Abstract: The most common form of drug-resistant epilepsy is mesial temporal lobe epilepsy (MTLE), where the temporal lobe structures are involved in seizure generation. MTLE is associated with aberrant networks even under resting state, suggestive of abnormal synaptic connections. Excessive glutamatergic synaptic activity is one of the mechanisms associated with epileptiform activity in patients with MTLE but it is not clear if the magnitude of alteration in glutamatergic tone remain homogenous throughout the temporal lobe. Measuring the excitatory transmission under resting state may provide valuable information about region specific functional networks. In this study we have performed resting state coherence analysis of magnetoencephalography data of patients with MTLE who were undergoing epilepsy surgery. This revealed two major epileptogenic networks, one emanating from the hippocampus and the other from the anterior temporal region (ATL). Whole cell patch-clamp technique was used to record spontaneous excitatory postsynaptic currents (EPSCs) under resting conditions from pyramidal neurons in slice preparations of resected samples from the hippocampal and ATL

region obtained from patients with MTLE. We observed a higher frequency and amplitude of EPSCs in both the samples compared to non-epileptic controls, while the frequency was significantly high in ATL samples even in comparison to the hippocampal samples. To isolate action potential (AP)-dependent EPSCs from AP-independent EPSCs we performed the recordings in the presence of Na^+ channel blocker, tetrodotoxin (TTX; 200 nM). TTX reduced the frequency of spontaneous EPSCs by 49.6 ± 4.3 % and 61.8 ± 6.2 % in the hippocampal and ATL samples, respectively, suggesting that the magnitude of contribution of AP-dependent excitatory activity is higher in the ATL region as compared to the hippocampus. Compared to non-epileptic controls, peak amplitude of miniature EPSCs was higher by 47.8 ± 4.3 % in the hippocampus and by 64.8 ± 5.4 % in the ATL samples indicating difference in the glutamate release probability in the two regions. We also found that the magnitude of upregulation of expression of NR2A subunit of the NMDA receptors was more in the ATL samples compared to the hippocampal samples. These findings altogether support the concept that mechanism of hyper excitability varies in the hippocampal and the ATL region of patients with MTLE, possibly mediated by two independent epileptogenic networks.**Support**: This work is supported by Department of Biotechnology, Ministry of Science & Technology, Government of India [Grant: BT/01/COE/09/08].

Title: Modulation of thalamic and cortical GABA transporter: the potential mechanism for the anti-absence activity of mGlu5 receptors.

Authors: R. CELLI[1], I. SANTOLINI[1], V. D'AMORE[1], A. PITTALUGA[2], *R. GRADINI[3,1], G. VAN LUIJTELAAR[4], G. BATTAGLIA[1], V. BRUNO[1,3], F. NICOLETTI[1,3], R. T. NGOMBA[5]; [1]I.R.C.C.S. Psychology, Donders Ctr. for Cognition, Radboud Univ., Nijmegen, Netherlands; [5]Univ. of Lincoln, Lincoln, United Kingdom

Abstract: Recent evidence suggests a protective role for Group I metabotropic glutamate receptors as potential candidates for the treatment of absence epilepsy. It has been demonstrated that acute treatment with positive allosteric modulators (PAMs) of mGlu1 and mGlu5

metabotropic glutamate receptors (RO0711401 and VU0360172, respectively) dose dependently reduces the incidence of spike-and wave discharges (SWDs), which are the EEG hallmarks of absence epilepsy, in spontaneously epileptic WAG/Rij rats. In addition, VU0360172 maintained its activity during chronic treatment, whereas rats developed tolerance to RO0711401 since the 3rd day of treatment and were still refractory to the drug two days after treatment withdrawal. VU0360172 was able to significantly reduce the incidence of SWDs when locally infused into the somatosensory cortex or the ventrobasal thalamus of WAG/Rij rats, and, interestingly, the action of intrathalamic VU0360172 was reversed by GABA transporter (GAT-1) inhibitor, tiagabine, infused in the thalamus at doses that did not affect SWDs on their own. On the basis of these findings, we have hypothesized that mGlu5 receptors regulate the expression and/or activity of GAT-1, and this specific mechanism might contribute to the role played by these receptors in the regulation of SWDs. We report here that a single injection of VU0360172 (3 mg/kg, s.c.) enhanced GAT-1 protein levels in the thalamus of symptomatic WAG/Rij rats (5 months of age), but did not change GAT-1 expression in the cerebral cortex or hippocampus. In contrast, no changes in thalamic GAT-1 expression were observed after 3 days of treatment with VU0360172 (3 mg/kg, s.c., bid), suggesting the development of tolerance. Curiously, a 3-day treatment with VU0360172 enhanced GAT-1 expression in the cortex and hippocampus. Identical findings were obtained in pre-symptomatic WAG/Rij rats (20-24 days of age) and in age-matched non-epileptic Wistar control rats, suggesting that the regulation of GAT-1 by mGlu5 receptors is not restricted to epileptic animals. Our data raise the possibility that activation of mGlu5 receptors controls the incidence of absence seizures by enhancing GABA uptake in the cortico-thalamo-cortical circuitry, thereby restraining the endogenous activation of $GABA_A$ and $GABA_B$ receptors.

Title: A novel fluorescent probe for monitoring extracellular pH shifts during neuronal hyperactivity

Authors: *M. CHIACCHIARETTA[1], S. LATIFI[1], M. FADDA[2], M. BRAMINI[1], A. FASSIO[2], F. CESCA[1], F. BENFENATI[1];
[1]Ctr. for Synaptic Neurosci. and Technol., Inst. Italiano Di Tecnologia, Genova, Italy; [2]Dept. of Exptl. Medicine, Univ. of Genova, Genova, Italy

Abstract: In the central nervous system changes in extracellular pH modulate neuronal excitability, membrane potential, synaptic transmission and neurotransmitter uptake. The correlation between pH shifts and neuronal hyperexcitability is well established, however, because of the lack of accurate systems able to measure extracellular H^+ concentration, addressing the detailed events underlying pH-induced modulation of neural excitability is still a major challenge. Monitoring these pH shifts with high time and spatial resolution could help to elucidate many physiological and pathological processes. The aim of the present study is to describe the i) spatio-temporal dynamics of extracellular pH during neuronal hyperexcitability, and ii) the mechanisms underlying this process. To address these issues we created ex.E^2GFP, a membrane-targeted extracellular ratiometric pH indicator exquisitely sensitive to acidic shifts. By monitoring E^2GFP fluorescence in real time in primary cortical neurons we were able to build a dose-response curve by switching the excitation wavelength between 405 and 488 nm and systematically adjusting the extracellular pH from 5.9 to 7.7. We, then, quantified pH fluctuations during network excitation induced by bicuculline or by high frequency stimulation. Our data demonstrated that during epileptic-like activity pH shifts take place both at synaptic regions and at the soma of neuronal cells, both at excitatory and inhibitory sites. These acidic shifts during intense neuronal activity imply non-quantal release of protons from neurons; this process could occur through distinct H^+ secreting/transporting mechanisms, including the Na^+/H^+ exchanger (NHE), which transports Na^+ into the cells and extrudes H^+. Interestingly inhibition of NHE by amiloride blocks bicuculline-induced extracellular acidification, without affecting the firing and bursting rates, thus highlighting a major role of NHE in the regulation of extracellular pH. In conclusion, the extracellular sensor engineered in this study will be instrumental to better understand ionic dynamics under physiological and pathological conditions with high spatio-temporal precision and accuracy.

Title: Involvement of toll-like receptor 2 in inflammatory responses and seizure generation in two mouse models of temporal lobe epilepsy

Authors: *Y.-W. HUNG[1,2], Y.-J. TSENG[4], Y.-C. WU[1,2], Y.-Y. LIN[1,2,3];
[1]Inst. of Brain Sci., Natl. Yang-Ming Univ., Taipei, Taiwan; [2]Lab. of Neurophysiol., [3]Cerebrovascular Dis. Section, Neurolog. Inst., Taipei Veterans Gen. Hosp., Taipei, Taiwan; [4]Dept. of Med. Res., Hsinchu MacKay Mem. Hosp., Hsinchu, Taiwan

Abstract: Objective: Neuroinflammation identified in epileptogenic tissue has been proposed to play central pathogenic roles in the development of neuronal cell death, reactive gliosis, aberrant neurogenesis and synaptic reorganization following epilepsy. Microglial cells are the principle immune cells in the innate immune system of central nervous system and their activation via toll-like receptor 2 (TLR2) has a pivotal role in pro-inflammatory responses associated with brain injury and some neurological diseases. Thus, it is hypothesized that seizure activities up-regulate TLR2 expression that might subsequently contribute to epileptogenesis. In the present study, we investigated the involvement of TLR2 in the development of epilepsy using two mouse models of temporal lobe epilepsy. **Methods:** Experimental epileptic seizures were induced by either pilocarpine or electrical amygdala kindling in both wild-type (WT) C57BL/6 mice and TLR2 knockout (TLR2 KO) mice. The TLR2 expression in the hippocampus was detected by immunohistochemistry and enzyme-linked immunosorbent assay. The effects of TLR2 inhibited neutralizing antibody, and of the genetic deletion of TLR2 on the development of epilepsy were evaluated. **Results:** In the epileptic hippocampus of WT mice, TLR2 was mainly expressed in microglia (Iba-1^{+}) in the regions of CA1, CA3 and dentate gyrus. Expression of TLR2 was significantly increased on day 7 after pilocarpine-induced status epilepticus. In the kindling model, the number of stimulations required to achieve fully kindled seizures was significantly decreased in the TLR2 KO mice compared to the WT mice. In addition, the TLR2 KO mice exhibited a shorter latency for seizure onset and higher after-discharge amplitude after electrical stimulation. Moreover, a reduced number of stimulation required to achieve fully kindled seizures was significantly decreased in the mice treated with TLR2 neutralizing antibody 30 min

prior to electrical kindling. In fully kindled mice, the relative threshold for seizure-induction showed a decreasing trend after TLR2 neutralizing antibody administration. **Conclusions:** Taken together, we assumed that TLR2 inhibition might promote kindling epileptogenesis and suggested that TLR2 participates in the generation of epilepsy.

Title: Role for 5-HT2C receptors in absence seizures: an electrophysiological and immunohistochemical study in GAERS and NEC rats

Authors: *G. DI GIOVANNI[1], M. VENZI[2], A. CAVACCINI[3], C. BOMBARDI[4], V. CRUNELLI[5];
[1]Physiol. and Biochem., Univ. of Malta, Msida, Malta; [2]AstraZeneca Translational Sci. Ctr. at Karolinska Institutet, Stockholm, Sweden; [3]Dept. of Neurosci. and Brain Technologies, Inst. Italiano di Tecnologia, Genoa, Italy; [4]Dept. of Vet. Med. Sci., Univ. of Bologna, Bologna, Italy; [5]Neurosci. Division, Sch. of Biosci., Cardiff Univ., Cardiff, United Kingdom

Abstract: Monotherapy with first-line anti-absence drugs only controls absence seizures (ASs) in 50% of patients, and there is therefore the need of novel therapeutic targets. In this study, we investigated the effect of selective 5-HT_{2C}R ligands on ASs in freely moving GAERS, a polygenic model of AS, and the modulation of tonic GABA-A current of ventral basal (VB) thalamocortical (TC) neurons as well as compared 5-HT_{2C}R and 5-HT transporter (SERT) expression in VB and perioral region of primary somatosensory cortex (PoS1) of GAERS and (non epileptic control) NEC strains. The 5-HT_{2C} agonist RO60-0175 suppressed ASs and normalized aberrant tonic current in GAERS VB TC neurons, an effect blocked by the selective 5-HT_{2C}R antagonist SB242084. Significant down-regulation of 5-HT_{2C}R-immunoreactivity (IR), but no difference in SERT-IR, was observed in VB and PoS1 of GAERS compared to NEC. In conclusion, 5-HT_{2C}Rs negatively control the expression of ASs in GAERS and decrease VB tonic GABA-A inhibition. Thus, dysregulation of 5-HT_{2C}Rs may be involved in the pathogenesis of absence seizures or a consequence of ASs. Crucially, selective 5-HT_{2C}R agonists might be potential novel anti-absence drugs.

Title: Role of Chd2 in cortical development and function

Authors: ***S. ABBASI**, J. C. FRANKOWSKI, S. LEE, K. GONZALEZ, S. SMITH, R. F. HUNT;
Anat. and Neurobio., Univ. of California, Irvine, Irvine, CA

Abstract: *De novo* mutations (or deletions) in the chromatin remodeler, Chd2, have been linked to a number of childhood brain disorders, such as epilepsy, intellectual disability, autism and/or photosensitivity. While increasing evidence supports a role of Chd2 in these disorders, how Chd2 mutations alter the function of individual subpopulations of neurons and ultimately brain circuits is unknown. To address the role of Chd2 deletion in cortical development, we generated a new floxed Chd2 transgenic mouse and crossed these animals to β-actin-Cre mice to produce Chd2+/- mutants. At P30, Chd2 was highly expressed in neurons (NeuN), including GABAergic interneurons (GAD67), but absent in putative astrocytes (GFAP) of wild-type animals. Western blot analysis showed a marked reduction of Chd2 protein in brain of Chd2 mutants. Patch-clamp recordings revealed an increase in excitatory synaptic input onto layer II/III pyramidal cells in somatosensory cortex of Chd2 mutants; intrinsic electrophysiological properties were unchanged. In addition, using a battery of behavioral tests, long-term video-EEG monitoring and immunostaining experiments, we are investigating the effect of Chd2 deletion in different cell types and at defined stages of forebrain development. Our results suggest cell type-specific impairments in cortical development and function may contribute to behavioral disturbances associated with Chd2 mutation.

Title: Neural activity propagation by endogenous electric field in the hippocampus *In vitro*

Authors: *R. SHIVACHARAN, D. DURAND;
Dept. of Biomed. Engin., Case Western Reserve Univ., Cleveland, OH

Abstract: It has been observed that epileptogenic agents generate fast-propagating waves that travel along the longitudinal pathway in the hippocampus. Recent studies in human epilepsy have described a similar phenomenon. We have previously shown that the fast-propagating wave travels at the speed of 0.12 m/s in the rodent hippocampi, which is not consistent with diffusion. In addition, these waves propagate in the absence of synaptic transmission and gap junction. These results indicate that the propagation mechanism is consistent with electric field transmission but do not provide direct evidence. The purpose of this study is to test the hypothesis that epileptiform activity propagates via electric field. We developed an extracellular field clamp (EFC) capable of measuring the local field and applying a current to cancel it. The experiments were carried out in a longitudinal hippocampal slice preparation with 4 Aminopyridine (4-AP) to generate spontaneous spikes observed to travel from the temporal to the septal region. Low-calcium solutions were applied to eliminate synaptic transmission. The EFC was located in the middle of the slice and the results show that spike could travel to the EFC but could not cross. This result supports the notion that electric field alone can be responsible for volume conduction of neural activity and that this haptic propagation could play a role in synchronization of epileptiform activity.

Title: Emergence of epilepsy in a transgenic mouse strain that overexpresses brain-derived neurotrophic factor in the forebrain

Authors: C. YEPES[1], M. LAQUERRE[1], W. ZHOU[1], K. GUTHRIE[1], *C. ISGOR[2];
[1]Biomed. Sci., [2]Charles E. Schmidt Biomed Ctrr, Florida Atlantic Univ. Charles E Schmidt Col. of Med., Boca Raton, FL

Abstract: Mice that overexpress brain-derived neurotrophic factor (BDNF) under the alpha-calcium/calmodulin-dependent protein kinase IIa promoter (termed TgBDNF mice) develop spontaneous seizures at ~6 months of age. Slow developing nature of behavioral disruptions observed in TgBDNF mice led to the hypothesis that chronic and sustained elevations in local BDNF are critical for progressive remodeling of hippocampal circuits implicated in epileptogenesis. We have previously shown that the mossy fibres (MF), axonal projections from the dentate gyrus granule cells (GCs) that innervate the CA3 field, are expanded in volume in TgBDNF mice compared to wildtype (WT) controls at 2-3 months of age coupled with increases in the molecular layer volume and dentate GC dendritic spine density. Increase in number of spines was observable in mushroom-type spines, suggesting that excess BDNF may be associated with increased synaptic input from entorhinal cortex onto GC dendritic arbors in mature circuitry even before seizure development. In this study, we monitored emergence of spontaneous seizures in the TgBDNF mice from 2 to 13 months of age to determine when seizures emerge and how severe and prevalent they become to assess the progressive nature of pathology. We also obtained electroencephalogram (EEG) recordings to demonstrate seizure profiles in cortical activity of epileptic mice. Lastly we tested for shifts in the balance of excitatory/inhibitory synaptic inputs to dentate GCs and CA3 neurons to determine emergence of hyperexcitable circuitry in the pre-seizure time period. Confocal imaging of presynaptic markers for excitatory or inhibitory synaptic proteins (VGLUT1, VGAT) are used to quantify densities of immunoreactive (IR) puncta in the molecular layer, stratum lucidum, stratum oriens, as well as granule and CA3 pyramidal cell layers. Puncta analyses are compared to those from 6-7 month-old TgBDNF mice that manifested seizures. 44% of TgBDNF mice displayed spontaneous seizures at ~6 months of age. This number increased to 85% of mice when animals mature to 12-13 months of age. The frequency and severity of seizures also increased with age, underlying the

progressive nature of epileptogenic processes. Epileptic seizures were marked with pre-ictal single spike events followed by ictal discharge, ending with EEG flattening that is associated with muscle stiffening (tonus) and loss of posture. The entire stage 5 seizure from pre-ictal spike events to background EEG recovery lasted about 30-60 sec. Animals recovered fully without any fatality. Our findings identify a progressive structure-function relationship with end point of epileptogenesis in the TgBDNF strain.

Title: Selective activation of somatostatin or parvalbumin expressing interneurons triggers GABA-mediated LLDs in rat neocortex

Authors: ***A. BOHANNON**[1], J. HABLITZ[2];
[1]Dept. of Neurobio., Univ. of Alabama At Birmingham, Birmingham, AL; [2]Neurobiol Dept, Univ. of Alabama at Birmingham, Birmingham, AL

Abstract: In the presence of the A-type K^+ channel blocker 4-aminopyridine (4-AP), long-lasting depolarizations (LLDs) occur spontaneously and propagate through the neocortex. These LLDs persist when excitatory glutamatergic neurotransmission is blocked with CNQX and D-APV (EAA blockers), suggesting the events arise from synchronous activity of inhibitory interneurons and represent a propagating GABA-mediated LLD. While this phenomenon is well documented, the role of specific interneuron (IN) classes in generating these events is poorly understood. Recently, we have shown that 4-AP alters the action potential and repetitive firing properties of Martinotti cells (MC) and fast-spiking basket cells (FS-BC) in neocortex, making these cells prime candidates for involvement in LLD initiation. In this study, we independently assessed the ability of MCs and FS-BCs to initiate LLDs using light-activation via genetically encoded channelrhodopsin (ChR) driven by the somatostatin (SST) or parvalbumin (PV) promoter, respectively. Spontaneous and light-initiated LLDs were recorded from putative Layer

2/3 MC, FS-BC and pyramidal cells in normal saline and following application of 4-AP and EAA blockers. In all cell types, wash-on of 4-AP and EAA blockers induced spontaneous LLDs and increased the amplitude and duration of light-triggered GABAergic events. The amplitude, duration, and response area of light-initiated LLDs in both PV:ChR and SST:ChR animals were statistically equivalent to spontaneous and evoked LLDs, suggesting activation of either interneuron class alone is sufficient to initiate cortical GABA LLDs. These results suggest synchronous GABAergic network activity is driven by neuronal ensembles consisting of multiple IN populations rather than being driven by a single cell type, implicating inter-population cooperativity in aberrant GABAergic activity in the neocortex.

Title: Defective synaptic vesicle recycling in epilepsy and developmental delay-associated de novo mutations of dynamin 1

Authors: *K. BONNYCASTLE[1], D. C. SOARES[2], W. W. K. LAM[2], M. A. COUSIN[1]; [1]Muir Maxwell Epilepsy Ctr. and Ctr. for Integrative Physiol., [2]Inst. of Genet. and Mol. Medicine, Western Gen. Hosp., Univ. of Edinburgh, Edinburgh, United Kingdom

Abstract: The large neuron-specific GTPase, dynamin 1, plays an essential role in synaptic vesicle (SV) recycling. During clathrin-mediated endocytosis (CME), dynamin 1 induces fission of the membrane through guanosine-5'-triphosphate (GTP) hydrolysis at the vesicle neck. Dynamin 1 also plays a role in the formation of vesicles from bulk endosomes, following activity-dependent bulk endocytosis (ADBE). We have identified *de novo* dynamin 1 mutations in patients with either epilepsy, developmental delay, or comorbid for both of these disorders. We hypothesized that these *de novo* mutations in dynamin 1 may alter SV endocytosis. We evaluated the impact of these mutations on the 3-D structure of dynamin 1. All mutations identified were predicted to be deleterious for dynamin 1 function. To determine whether these mutations impacted on the synaptic role of dynamin 1, we used the genetically encoded

reporters, synaptophysin-pHluorin (sypHy) and vesicle associated membrane protein 4-pHluorin (VAMP4-pHluorin) to visualize both CME and ADBE in embryonic mouse hippocampal neurons. Intriguingly, we identified that specific dynamin 1 mutants had differential effects on both CME and ADBE. These defects in SV endocytosis may therefore underlie some of the symptoms displayed by these patients. They also suggest that dysfunctional SV endocytosis may be a common underlying event across different neurodevelopmental disorders, providing a novel avenue for future treatment strategies. Finally, these studies provide further insight regarding the potentially divergent molecular role(s) of dynamin 1 in presynaptic function.

Title: Selective inhibition of inflammatory cascades following experimental febrile status epilepticus

Authors: *M. M. CURRAN, K. P. PATTERSON, M. SARGIOUS, T. Z. BARAM;
Univ. of California Irvine, Irvine, CA

Abstract: Rationale: Epilepsy is a common neurological disorder, effecting ~1% of the world's population. Temporal lobe epilepsy (TLE) is a common form of epilepsy, and is often preceded by trauma or long febrile seizures (febrile status epilepticus, FSE) (French et al., 1993; Dubé et al., 2007). However, how the insult, including FSE, promotes epilepsy is unknown. Inflammation is involved in fever and FSE and is among candidate mechanisms for epileptogenesis (Vezzani, et al., 2011). Using a model of experimental FSE, we have previously shown that FSE is sufficient to directly cause TLE in a subset of immature rodents (Dube, et al., 2006, 2010) and have found a strong correlation of inflammatory cytokine expression and epilepsy-predicting limbic MRI changes (Patterson, et al., 2015). This prompted the hypothesis that early, selective interference with initial steps of inflammatory pathways would prevent later-phase inflammatory mediators and abort the epileptogenic processes. Because global elimination of inflammation was not helpful (Patterson, et al., in prep), we focused on High Mobility Group Box 1 (HMGB1) and EP2 prostaglandin E_2 (PGE_2) receptor as potential therapeutic targets.

Methods: Experimental FSE was induced in post-natal day 10-11 Sprague Dawley rat pups as previously described (Choy, et al, 2014). Briefly, pups were exposed to a continuous stream of warm air to induce behavioral seizures. Elevated core temperatures and seizures were maintained for 60 minutes. In the first experiment, FSE or normothermic control rats were given intracerebroventricular infusions of vehicle or HMGB1 Box A, a direct antagonist of HMGB1 (Maroso, et al., 2010). In the second experiment, rats were either given intraperitoneal injections of vehicle or TG6-10-1, a specific EP2 (a PGE_2 receptor) antagonist (Jiang et al., 2013). In both experiments, experimental rats or same litter naïve controls were then sacrificed and their hippocampi were extracted. qRT-PCR was used to quantify expression changes in inflammatory mediators.
Results: At both early time points (3 hrs) and later (24-96 hrs), there was robust activation of both the HMGB1- and PGE_2-dependent inflammatory pathways. This included elevations of Tumor Necrosis Factor-Alpha (TNFα), Inhibitor of Kappa B-Alpha (IκBα), Cyclooxygenase 2 (COX2) and membrane bound PGE-synthase 1 (mPGES1). Blocking HMGB1 binding to target receptors had little effect on the expression of HMGB1 dependent molecules as compared to both controls and FSE-vehicle animals. Experiments employing TG6-10-1 are ongoing.

Title: The role of gluk2-containing kainate receptors in acute hypoxic seizures in the neonatal mouse.

Authors: *S. A. ZANELLI[1], P. WAGLEY[2], D. GROSENBAUGH[2], J. KAPUR[2];
[1]Pediatrics, Univ. of Virginia, Charlottesvle, VA; [2]Neurol., Univ. of Virginia, Charlottesville, VA

Abstract: Background: Kainate receptors (KARs) are differentially expressed in the brain during development and peak in the late embryonic/early postnatal period. Recent evidence supports the role of KARs, specifically those containing GluK2, in the pathogenesis of epilepsy. However, how KARs activation following hypoxia regulates synaptic transmission and seizures in the immature brain is not known.
Objective: To test the hypothesis that activation of KARs by glutamate during hypoxia alters synaptic transmission leading to increased seizure susceptibility in the neonatal mouse and that GluK2-containing KARs mediate, at least in part, these effects.
Methods: The effects of KAR-blockade on synaptic transmission were studied in an *in vitro* asphyxia model (oxygen glucose deprivation [OGD]). Miniature excitatory post-synaptic currents (mEPSCs) and miniature inhibitory post-synaptic currents (mIPSCs) were measured in CA1 pyramidal neurons in P7-10 mice. KARs were pharmacologically isolated using DL-AP5 (NMDA receptor antagonist), GYKI53655 (α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (AMPAR) antagonist), UBP310 (KAR antagonist) or CNQX to block both AMPARs/KARs. Seizure generation following acute hypoxia (4min30secx4 min) was then studied in wild-type, GluK2 $^{-/-}$ and mice pre-treated with UBP310 (5-75 mg/kg, 30 min prior).
Results: mEPSC frequency increased during both OGD and reoxygenation. In the presence of UBP310, the increase in mEPSC frequency was abolished and instead a decrease in mEPSC frequency occured (0.36±0.04 Hz at baseline vs. 0.23±0.02 Hz during reoxygenation; p=0.0005). Further, exposure to OGD in the presence of GYKI53655 resulted in decreased mIPSC frequency during reoxygenation (0.362±0.06 Hz at baseline vs. 0.285±0.06 Hz during reoxygenation; p=0.0003). This decreased mIPSC frequency was not observed in similar experiments performed in the presence of CNQX to block AMPARs and KARs. Gluk2$^{-/-}$ mice were less susceptible to acute hypoxia with seizures during reoxygenation in 33.3% of pups vs. 80% in controls ($p<0.05$). Similarly, mice treated with UBP310 experienced less post-hypoxic seizures in a dose dependent manner with highest efficacy observed with 75 mg/kg (80% vs. 42.8%, $p<0.001$).
Conclusions: These results suggest that activation of GluK2-containing KARs during hypoxia represent an important mechanism of increased excitability in the neonatal brain. Further, KAR blockade leads to enhanced glutamatergic synaptic transmission while decreasing inhibitory synaptic transmission in the CA1 region of the hippocampus, emphasizing the role of KARs in the pathophysiology of neonatal hypoxic seizures.

Title: Different electrographic epileptic discharge types associated with absence epilepsy are interrelated in rat association cortex.

Authors: *S. HALL[1], M. A. WHITTINGTON[1], R. D. TRAUB[2];
[1]Univ. of York, York, United Kingdom; [2]IBM T.J. Watson Res. Ctr., Dept. of Physical Sci., Yorktown Heights, NY

Abstract: Introduction
Spike and wave-like discharges (SpW) are a feature of many absence-type epilepsies. They can present in many forms, with some SpW types being linked to pathology of the thalamocortical axis. Here we demonstrate the generation of, and interrelationship between varying forms of SpW discharges in the neocortex, using a combination of *in vitro* electrophysiology and biologically realistic computational modelling.
Results
Slow SpW discharges were generated on a background of sleep-associated delta rhythms by a reduction of tonic neuromodulatory excitation of peptidergic inhibitory interneurons, mediated by nACh and/or 5HT3A receptors. This caused an increase in amplitude and slowing of the delta rhythm (the 'wave' component) generated by deep layer pyramidal cells, and a switch from single spike to burst discharges in superficial layers (the 'spike' component). SpW discharges were transformed into polyspike and wave (polySpW) discharges via two methods. First, the altering of the bias from NPY-mediated to VIP-mediated superficial peptidergic inhibitory interneurons was enhanced by targeting the specific peptides involved. This led to rapid disinhibition of the superficial layers, further increasing the superficial pyramidal cell output and leading to the generation of polySpW events. Second, an increase in deep- to superficial synaptic excitation, achieved through theta-burst stimulation of the deep layers, also led to the generation of polySpW events. The two polySpW models were distinguishable by the inter-spike intervals on each event. Peptidergic disinhibition resulted in short-interval (91.7 +/- 3.0 ms) polyspike discharges whereas theta-burst stimulation of the deep- to superficial pathway led to long-interval polyspike discharges (129.3 +/- 3.4 ms). The subtle difference in interspike intervals was accompanied by dramatic differences in interlaminar interactions: Granger causality estimates indicated that long-interval polySpW discharges were initiated in deep layers, influencing the

spikes seen in superficial layers.The converse was true for the short-interval polySpW discharges.
Conclusions
These data suggest at least two possible mechanisms behind the generation of polySpW events; 1) selective loss of inhibition in superficial layers of neocortex and 2) an increase in deep neuronal excitation of superficial layers, through an enhancement of deep to superficial excitation. Both polySpW types grossly interfered with the interlaminar dynamics associated with normal delta rhythms.

Title: Collagen VI extracellular matrix protein modulates short-term plasticity in the hippocampus: Implications for epileptogenesis.

Authors: *T. RAMOS-MORENO[1,2], A. CIFRA[2], L. NIKITIDOU-LEDRI[3], S. H. CHRISTIANSEN[3], C. GØTZSCHE[3], M. CESCON[4], P. BONALDO[4], D. P. WOLDBYE[3], K. MERAB[2];
[1]Wallenberg Neurosci. Center/Stem Cell Ctr., Lund, Sweden; [2]Lund Univ., Epilepsy Center, Sweden; [3]Univ. of Copenhagen, Copenhagen, Denmark; [4]Univ. of Padova, Padova, Italy

Abstract: Extracellular matrix (**ECM**) molecules modulate several aspects of synaptic plasticity in the central nervous system (**CNS**) through multiple mechanisms that ultimately affect learning and memory. Collagen VI (**CVI**) belongs to the category of ECM protein and is primarily known for its bridging role in connective tissues. Here we report that the mRNA and protein levels of Collagen VI (**CVI**) are increased in the rat hippocampus at 4 weeks after the initial insult in post *status epilepticus* model of chronic epilepsy. In addition, we further explore whether CVI plays a

role in synaptic plasticity and if it can functionally affect neuronal networks in the hippocampus. Surprisingly, we detect an increased basal synaptic transmission after exposing rat hippocampal slices to CVI for 2 h and paired-pulse facilitation in Schaffer collateral-CA1 excitatory synapses after incubating hippocampal slices with CVI for 6 h, whilst CVI deficient mice exhibited paired-pulse depression, the opposite effect. These data suggest that CVI may decrease overall release probability in Schaffer collateral-CA1 synapses and, since CVI protein levels are augmented in post-*status epilepticus* animals, this could help in counteracting increased excitability in epileptic neuronal circuits.

Title: Structure and function of sprouted mossy fiber synapses in epilepsy.

Authors: *W. HENDRICKS[1,2], A. L. BENSEN[1], G. L. WESTBROOK[1], E. SCHNELL[2,3]; [1]Vollum Inst., Portland, OR; [2]Anesthesiol. and Perioperative Med., Oregon Hlth. and Sci. Univ., Portland, OR; [3]Portland VA Med. Ctr., Portland, OR

Abstract: Temporal lobe epilepsy is a debilitating chronic condition that can develop after various neurological insults, including traumatic brain injury, stroke, and infection. The exact mechanism driving the development of epilepsy has remained elusive. In the hippocampal dentate gyrus, seizures drive pathologic retrograde sprouting of granule cell mossy fiber axons.

Although sprouting may contribute to epileptogenesis, the physiologic consequences of mossy fiber sprouting are unknown. The dentate gyrus is a locus for adult neurogenesis and adult-born granule cells might directly give rise to sprouted mossy fibers, though this is widely debated and unresolved. If sprouted mossy fibers do primarily arise from adult-born dentate granule cells, then neurogenesis might play a role in establishing these aberrant connections. Using the pilocarpine model of epilepsy and transgenic labeling of age-defined cohorts of granule cells in mice, we demonstrate that adult-born neurons contribute to sprouting and are more likely to develop sprouted mossy fibers than their neonatally-born counterparts. Using super-high resolution confocal microscopy, we demonstrate these synapses form large and highly complex synapses onto dendritic shafts and spines. Furthermore, using optogenetics to drive granule cell firing, we find that sprouted mossy fibers drive recurrent excitation. When activated, these pathological synapses are capable of triggering firing of granule cells and propagating reverberating excitation throughout the dentate gyrus. Taken together, these data suggest that adult-born neurons may play a significant role in epileptogenesis through their contribution to mossy fiber sprouting.

Title: Potential role of β-amyloid peptides in kainic acid-induced toxicity

Authors: *D. I. OURDEV, A. KODAM, M. MAULIK, Y. WANG, M. BANERJEE, S. KAR; Univ. of Alberta, Edmonton, AB, Canada

Abstract: Kainic acid (KA), a degradation-resistant analogue of the excitatory neurotransmitter glutamate, is known to trigger seizures in rat models which originate from the hippocampus and can spread to other limbic structures. This is associated by the subsequent loss of neurons, mossy fiber reorganization, and astrogliosis, pathologies which closely mimic those characteristic of human temporal lobe epilepsy (TLE). KA exerts its epileptogenic effects through the activation of kainate receptors (KA-Rs) which generate synchronized network-driven glutamatergic currents. Nevertheless, the underlying cellular mechanisms by which KA triggers

neurodegeneration remains unclear. A number of recent studies indicate that amyloid β (Aβ), the peptides critical for their involvement in Alzheimer's disease (AD) pathogenesis, may play a potential role in triggering seizures and the associated loss of neurons. These peptides are generated from the constitutively expressed amyloid precursor protein (APP), which is alternately processed by the non-amyloidogenic α-secretase or amyloidogenic β-secretase proteolytic pathways. However, very little is known regarding the involvement of Aβ peptides in KA-induced toxicity. To address this issue, we evaluated time-dependent alterations in the levels and cellular distribution of APP and its processing enzymes in the hippocampi of KA-treated rats. We report that KA triggers a significant increase in APP processing in proliferating astrocytes. Additionally, using rat primary hippocampal neuronal cultures, we are currently evaluating the significance of Aβ peptides in the degeneration of neurons. Our results reveal that increased endogenous levels of APP may have a role in triggering degeneration of neurons in animal models of TLE.

Title: Regulation of synaptic transmission by mTORC1 and mTORC2.

Authors: *M. MCCABE, C. BARROWS, M. C. WESTON;
Dept. of Neurolog. Sci., Univ. of Vermont, Burlington, VT

Abstract: The mammalian target of rapamycin (mTOR) signaling cascade regulates cellular growth, proliferation and protein synthesis. Hyperactivation of mTOR in the central nervous system of both humans and animal models can lead to cortical malformations, cognitive disabilities, autistic behavior and epilepsy. In addition, the mTOR pathway may be abnormally activated by acquired injuries that produce epilepsy and trigger downstream processes of epileptogenesis. Therefore, a more complete understanding of how the mTOR pathway regulates fundamental aspect of neuronal function may provide new targets for therapeutic intervention early on or even prior to the onset of neurological symptoms. Pten is a negative regulator of the PI3K-mTOR signaling pathway whose loss of function causes mTOR hyperactivation. Deletion

of Pten in subsets of neurons leads to macrocephaly, autism-like behavior and seizures. Previous studies of synaptic transmission after genetic or pharmacological manipulation of the mTOR signaling cascade, and Pten in particular, have reported alterations in synaptic transmission and plasticity. Specifically, Pten loss leads to enhanced synaptic currents in both glutamatergic and GABAergic neurons, and increases in both the number of synaptic vesicles in the readily releasable pool and the postsynaptic response to single vesicle fusion are underlying mechanisms. 72 hour treatment with rapamycin completely blocked these changes and caused an additional increase in the probability of synaptic vesicle fusion. The goal of the present research was to explore the role of mTOR complex 1 (mTORC1) and mTOR complex 2 (mTORC2) in mediating these effects. We selectively impaired mTORC1 or mTORC2 in cultured hippocampal neurons by genetic deletion of Raptor or Rictor, association proteins necessary for the formation of mTORC1 and mTORC2 respectively. We observed a reduction in peak evoked EPSC (eEPSC) amplitude following Raptor or Rictor knockout, as well as a reduction in the size of the synaptic vesicle readily releasable pool (RRP) following Raptor knockout. When both Raptor and Pten were deleted, peak eEPSC amplitude and RRP size resembled wild-type cells. Taken together, these observations indicate that mTORC1 and 2 play dissociable roles in regulating synaptic transmission, and loss of mTORC1 alone can rescue the synaptic effects of Pten knockout.

Title: Hippocampal hypermetabolism following kainic acid administration in awake and anesthetized rats: FDG-PET study

Authors: *T. BERDYYEVA, Y.-C. HSIEH, S. YUN, J. SHELTON, C. DUGOVIC, H. KOLB, A. SZARDENINGS;
Janssen, San Diego, CA

Abstract: The effectiveness of novel anti-epileptic drugs (AEDs) is often judged by their effectiveness in reducing the severity of behavioral and electroencephalographic (EEG) signs of seizures in animal models. However, behavioral and EEG assessment provide limited insight into the extent of the seizure-related pathological changes within the relevant brain structures. Therefore, the selection of medication is often biased toward agents reducing seizure symptoms

rather than alleviating the seizure-related brain pathologies. Here, we demonstrate the use of the non-invasive brain imaging technique - positron emission tomography (PET) - in conjunction with EEG and behavioral monitoring as a screening tool to select treatments that not only alleviate seizures, but also lessen seizure-related pathological changes within the brain.
We used PET imaging to measure seizure-induced changes in the standardized uptake values (SUV) of [F18] fludeoxyglucose (FDG) in rats that behaved freely for 30 minutes following kainic acid (KA, 12 mg/kg, i.v.) administration ("uptake in awake", n = 10, static scan for 30 minutes). The electrographic seizure activity was confirmed via EEG recordings, and the behavioral seizure scores were recorded every 2 minutes. We observed that KA administration reliably, consistently and significantly elevated FDG uptake in the hippocampus relative to control (SUV changed from 3.56 to 4.78, 33% increase, p =0.005, t-test). To investigate the time course of the pathological hippocampal hyperactivity following KA administration, we performed a dynamic scan (60 minutes; the data were binned in 10-minute intervals) in rats that were continuously anesthetized ("uptake in anesthetized", n = 4). Similarly to the "uptake in awake", KA – treated rats showed increased FDG uptake in hippocampus, with the difference becoming significant 35, 45 and 55 minutes post-KA administration ($p< 0.05$, 0.01, 0.001 respectively). Interestingly, a standard treatment to alleviate KA-induced seizures in rat (combination of Ketamine, 50 mg/kg, i.p. and Diazepam, 20 mg/kg, i.p.) did not alleviate hippocampal hyperactivity in either group of animals, despite reducing KA-induced seizure severity.
These results demonstrate the presence of pathological hippocampal hypermetabolism not only in awake rats, but also in rats that were continuously anesthetized. Integrating non-invasive PET imaging with traditional assessment of seizures could potentially increase translatability of the drug screening process, leading to novel therapeutics designed to target and abolish abnormal patterns of both electrical and metabolic activity.

Title: Cannabidiolic acid controls seizure-like activity and neuronal excitability

Authors: *M. HOSSEINI ZARE[1], A. ABDULLA[1], K. AKULLA[2], J. ZIURKUS[1];
[1]Biol. and Biochem., Univ. of Houston, Houston, TX; [2]Ultragenyx Pharmaceut. INC., Novato, CA

Abstract: Intoxicating tetrahydrocannabinol (THC) and non-intoxicating cannabidiol (CBD) are the two most prevalent phytocannabinoids found in *cannabis sativa* plants. CBD is well studied in multiple disease models, especially as anti-convulsant in treatment of intractable forms of epilepsy. However, in many strains of cannabis, over 90% of phytocannabinoids are synthetized as non-intoxicating acidic cannabinoids. 'Raw hemp oil' extracts prepared using cold temperatures are often dominated by acidic cannabinoids, such as cannabidiolic acid (CBDA), which is the precursor of CBD. Recent evidence suggests that CBDA is an effective anti-emetic (acting through serotonin receptors), anti-inflammatory (Cox-2 inhibition), and it abrogates cancer cell growth. However, it is unknown what role CBDA plays in the central nervous system (CNS) and there is an urgent need to understand the functions of the acidic cannabinoids. Using single cell and network electrophysiological recordings, we compared effects of synthetic CBD (30μM) and CBDA (25μM) on seizure-like activity and neuronal excitability in the hippocampal slices. Both, CBD and CBDA reduced zero magnesium-induced seizure-like activity by reducing action potential firing in the excitatory pyramidal cells. CBDA actions were typically as effective, but delayed by 10-15 minutes, compared to CBD. Only CBDA significantly increased afterhyperpolarizations following the action potentials. In summary, our studies reveal new knowledge about the mechanisms of actions of CBDA in the brain. Further studies of CBDA and other acidic cannabinoids are needed to determine their effectiveness and therapeutic potential in vivo.

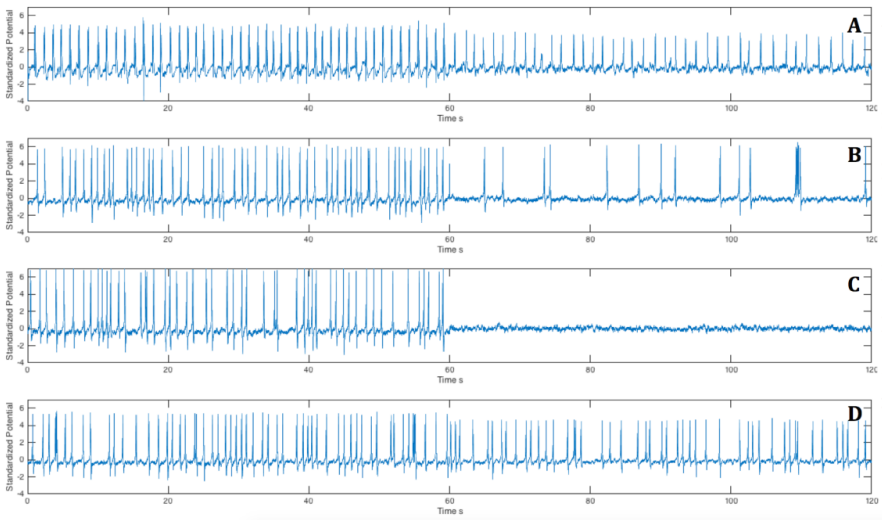
Title: A temperature-dependent neural mass model for suppression of epileptic discharges

Authors: ***J. SORIANO**[1,2], T. KUBO[1], T. INOUE[3], H. KIDA[3], T. YAMAKAWA[4], M. SUZUKI[3], K. IKEDA[1];
[1]Nara Inst. of Sci. and Technol., Nara, Japan; [2]Univ. of the Philippines - Diliman, Quezon City, Philippines; [3]Yamaguchi Univ., Ube, Japan; [4]Kumamoto Univ., Kumamoto, Japan

Abstract: An estimated fifty million people across the world currently live with epilepsy and suffer from seizures. Treatment for epilepsy ranges from anticonvulsants to invasive brain surgeries. Absolute remission however is not necessarily guaranteed. Focal brain cooling has been pursued and critically reviewed in the past decade as an alternative treatment for cases of refractory epilepsy. Previous research works with animal and human have suggested that cooling of the focal brain area significantly suppresses epileptic discharges. This observation is coincident with reduced concentration of neurotransmitters such as glutamate, which can be translated to reduced average synaptic gain of neural mass populations. In this study, we test whether this reduced concentration of neurotransmitters is a responsible mechanism for the effect of focal brain cooling via a temperature-dependent neural mass model using Q_{10} temperature coefficient. Wendling's model is used for its ability to reproduce multiple activity patterns observed in intracranial EEG only by changing average synaptic gains of dendritic and somatic inhibitory populations. Reduced neurotransmitter concentration is incorporated in the model using a Q_{10} factor in the conversion of input firing rate to average postsynaptic potential via a transfer function. We find that increasing Q_{10} factor values from 1.0 (no temperature dependence) decreases the frequency of epileptic discharges until complete termination. However, this does not capture persistent albeit suppressed epileptic discharges observed in EEG activities of drug-induced epilepsy in rats. This result suggests that a different mechanism is required to reproduce the observed effect of focal brain cooling. In additional analysis, we introduce a different Q_{10} factor in the conversion of input potential to average firing rate via a sigmoid function. Our results show that this model mimics suppression of epileptic discharges

during cooling as observed in the experiments implying that multiple responsible mechanisms may explain the effect of focal brain cooling.



A: EEG activity of induced epilepsy in rat brain before cooling (0s-60s) and during cooling (60s-120s) with T=20 ºC.
B: Model 1 with a Q_{10} factor of 1.006 in the transfer function. Frequency of epileptic discharges is reduced.
C: Model 1 with a Q_{10} factor of 1.013 in the transfer function. Epileptic discharges are completely terminated.
D: Model 2 with Q_{10} factors of 1.1 in the transfer function and 1.0985 in sigmoid function. This model replicates observed suppression of epileptic discharges.

Title: Cannabidiol increases inhibitory transmission and rescues social deficits in a mouse model of Dravet Syndrome

Authors: ***J. KAPLAN**[1], W. A. CATTERALL[2], N. STELLA[2], R. E. WESTENBROEK[2]; [1]Dept. of Pharmacol., [2]Pharmacol., Univ. of Washington, Seattle, WA

Abstract: Heterozygous mutations in the *Scn1a* gene encoding the brain type-1 voltage-gated sodium channel Nav1.1 cause Dravet Syndrome (DS), a severe childhood disorder characterized by treatment-resistant epilepsy, cognitive deficits, and autism spectrum disorder (ASD). As DS

symptoms result from the selective reduction of inhibitory interneuron excitability, therapeutic strategies that enhance interneuron excitability may effectively treat symptoms of DS. The phytocannabinoid, cannabidiol (CBD; GW Pharma; 10 mg/kg) represents a promising treatment for seizures that develop in DS, but its effects on ASD and cognitive impairment remain unknown. Here, we tested CBD's effects on ASD-like social deficits and on underlying physiological mechanisms in a mouse model of DS. *Scn1a*$^{+/-}$ mice (DS mice) phenocopy the core epilepsy, cognitive deficits, and ASD-like behavioral phenotypes associated with DS. CBD reduces seizure severity and duration in DS mice (Westenbroek et al., accompanying abstract), so we hypothesized that this compound may also reduce ASD behaviors in DS mice by restoring excitability to inhibitory interneurons. We tested this hypothesis using behavioral assays in which DS mice have well-characterized deficits, as well as patch-clamp electrophysiology of acutely dissected hippocampal slices in vitro. In the 3-Chamber Test, CBD improved the ratio of time DS mice spent in social interaction with a novel mouse compared to an empty cup. In the Reciprocal Interaction Test, CBD increased the number of social interactions and reduced defensive escape behaviors. These results suggest that CBD increased sociability and reduced social anxiety in DS mice. Next, we tested the effect of 16 μM CBD on excitatory and inhibitory input to DS mouse dentate gyrus granule cells. CBD increased the frequency of action potential (AP)-driven spontaneous inhibitory postsynaptic currents and reduced the frequency of spontaneous excitatory postsynaptic currents, without affecting amplitude. CBD reduced AP frequency in dentate granule cells in response to injection of depolarizing current below rheobase, but it had no effect on AP firing properties in response to depolarizing current above rheobase. Our results suggest that CBD rescues ASD-like behaviors and epileptic seizures by rebalancing the brain's excitatory/inhibitory ratio, primarily by enhancing inhibitory interneuron excitability, and thus represents an effective therapeutic strategy to rescue ASD behaviors in DS. Future experiments will test the effect of CBD on cognitive parameters and assess CBD's actions directly on interneuron firing properties.

Title: Cannabidiol reduces the duration and severity of thermally evoked seizures in a mouse model of Dravet Syndrome

Authors: *R. E. WESTENBROEK[1], J. S. KAPLAN[2], N. STELLA[2], W. A. CATTERALL[2]; [1]Pharmacol., Univ. Washington, Seattle, WA; [2]Pharmacol., Univ. of Washington, Seattle, WA

Abstract: Dravet Syndrome (DS) is one of the most severe childhood neuropsychiatric diseases, with intractable epilepsy, febrile seizures developmental delay, ataxia, sleep disorder, autistic-like behaviors, frequent premature death and profound cognitive deficit. Clinical and preclinical results suggest that cannabidiol (CBD), a non-psychoactive ingredient produced by the *Cannabis* plant has antiepileptic effects that act through a novel mechanism of action. We tested the hypothesis that CBD reduces thermally evoked seizures in mice that have heterozygous loss-of-function mutations in the *Scn1a* gene encoding Nav1.1 voltage-gated sodium channels and have been shown to accurately phenocopy DS. DS mice were treated with increasing concentrations of CBD (GW Pharma) or vehicle one hour prior to raising their body temperature one-half of a degree every two minutes up to 38^{o}C (similar to a low fever) and then holding this temperature for 30 min. We found that CBD at 100 mg/kg and 200 mg/kg reduced the duration of thermally evoked seizures in DS mice but had no effect on the temperature dependence of evoked seizures. Additionally, CBD reduced the severity of thermally evoked seizures from a Racine score of 5.0 to less than 4.0. With this significant reduction in Racine score, DS mice are no longer at high risk for sudden unexpected death in epilepsy (SUDEP). Collectively, these results suggest that CBD may be an effective therapeutic agent for thermally evoked seizures associated with DS. The effects of CBD on social behavior inherent in the DS phenotype and on possible underlying mechanisms are reported by Kaplan et al. (accompanying abstract). Title: Anticonvulsant, antiepileptic and neuroprotective effects of ketamine, valproate and midazolam polytherapy against soman exposure in rats

Authors: *L. A. LUMLEY[1], F. ROSSETTI[2], M. F. STONE[1], C. R. SCHULTZ[1], M. Q. PHAM[1], J. NIQUET[3], C. WASTERLAIN[3];
[1]USAMRICD, Gunpowder, MD; [2]Walter Reed Army Inst. of Res., Silver Spring, MD; [3]UCLA-West LA VAMC, Los Angeles, CA

Abstract: Introduction: Chemical warfare nerve agents (CWNA), such as soman (GD), produce *status epilepticus* (SE), resulting in extensive neuropathology and long-term performance deficits if seizures are not controlled. Current treatments for GD exposure increase survival, but are not fully protective especially when treatment is delayed. To identify a better treatment against pharmaco-resistant seizures caused by GD exposure, we are using combinations of drugs aimed at reversing the effects of maladaptive receptor trafficking that follows CWNA exposure. Methods: Rats were implanted with telemetry transmitters for continuous monitoring of EEG, body temperature and activity. After surgical recovery, rats were exposed to 1.2 LD_{50} GD and treated 1 min later with atropine sulfate and the oxime HI-6 and then 40 min after seizure onset with the histone deacetylase (HDAC) inhibitor valproate (VAL) with or without the NMDA antagonist ketamine (VAL/KET), the benzodiazepine midazolam (VAL/MDZ) or a combination of all three drugs (VAL/KET/MDZ). Two weeks after exposure, rat brains were sectioned and stained for neuropathology assessments. Results: Triple therapy with VAL/KET/MDZ reduced total time spent in seizures (SE + early recurrent seizures) in the first 72 h and reduced the number of spontaneous recurrent seizures compared to saline-treated or to those that received monotherapy or bi-therapy. Triple therapy prevented the development of hyperactivity that occurs in the weeks after GD exposure. In addition, triple therapy prevented loss of GABA interneurons in the piriform cortex and amygdala and loss of neurons in the piriform cortex, thalamus and amygdala that follows GD exposure. Conclusion: Triple therapy with VAL/KET/MDZ had remarkable anticonvulsant, antiepileptic, and neuroprotective effects compared with mono- or bi-therapy in GD-exposed rats. Triple therapy may be a highly effective approach against pharmacoresistant seizures, such as those caused by GD-exposure and may allow for use of lower doses with fewer side effects than those often seen with large doses of individual drug therapies. *Disclaimer:* The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Army, Department of Defense, or the U.S. Government. Title: Retrospective analysis of acute seizure management of 215 pediatric cases with intravenous levetiracetam

Authors: *B. F. KIRMANI, ESQ[1,2], P. LAKIREDDY[3], M. DANG[4], A. SARODE[5], S. LONG[5], P. PATEL[5], O. KHAN[3];
[1]neurology, T, Georgetown, TX; [2]Neurol., Scott and White Epilepsy Center, Baylor Scott and White Health/ Texas A& M Univ. HSC Coll of Med., Temple, TX; [3]Pediatrics, Baylor Scott and White Hlth., Temple, TX; [4]Texas A & M Col. of Med., Temple, TX; [5]Baylor Univ., Waco, TX

Abstract: Introduction: Children with intractable epilepsy have frequent hospital admissions because of status epilepticus and acute repetitive seizures. Seizures are also seen in the neonatal period and are a major indicator of future adverse neurological sequelae. Intravenous (IV) levetiracetam became available in August 2006 in patients aged 16 years and above. There is not enough data about safety and tolerability in children. We retrospectively analyzed data at our institution of children who received IV levetiracetam for acute seizure management. Objective: The goal of this study is to retrospectively assess the efficacy and tolerability of IV levetiracetam therapy in acute seizure management in children. Methods: A retrospective chart review was conducted on all preterm neonates, term neonates, and children less than 18 years of age who received IV levetiracetam at Scott and White Hospital/Texas A & M HSC College of Medicine, Temple, TX. Subject data were acquired from electronic medical records. Approval of this retrospective analysis was given by our hospital's Institutional Review Board. Results: We retrospectively analyzed 215 patients who met our inclusion criteria for neonatal seizures, status epilepticus and acute repetitive seizures and received IV levetiracetam. There were 119 (55.34%) males and 96 (44.65%) females. The loading dose of IV levetiracetam was 50 mg/kg in most patients, followed by a maintenance dose of 25 mg/kg every 12 hours. The dose was infused over 15 minutes to an hour. The primary objective was to assess response based on clinical and electro graphic documentation. The secondary objective was to assess the indication of initiation of this medicine, adverse events, and seizure control at well child visits. Response to levetiracetam was favorable. 185 (86%)out of 215 patients reached seizure freedom within 24 hours and 16 (7.44%) within 72 hours. Seizures continued after 72 hours in 14 patients requiring additional anticonvulsants. No serious side-effects were apparent. No serious adverse events were reported with any of the patients, 35 patients (20.7%) reported behavioral changes (irritability) while on levetiracetam. 14 patients were lost to follow-up . Patients were switched to oral levetiracetam after discharge from the hospital . The duration of follow up ranged from 6

months to 5 years. Conclusions: IV Levetiracetam seems to be efficacious and tolerable in acute seizure management in children.

Title: Ganaxolone and diazepam administered IV produce a synergistic anti-epileptic effect in a treatment refractory model of status epilepticus

Authors: *M. S. SAPORITO[1], J. A. GRUNER[2], J. TSAI[1], A. PATRONEVA[1];
[1]Marinus Pharmaceuticals, Inc., Radnor, PA; [2]Melior Discovery, Inc., Exton, PA

Abstract: Ganaxolone (GNX) is the 3β-methylated analog of the naturally occurring neurosteroid allopregnanolone that acts as a positive allosteric modulator of the $GABA_A$ receptor. GNX differs from the benzodiazepine class of $GABA_A$ modulators in that it enhances the activity of both the synaptic (comprised of α and γ subunits) and extrasynaptic $GABA_A$ receptors (comprised of α and δ subunits). The benzodiazepine sensitive synaptic $GABA_A$ receptor rapidly desensitizes during seizures and with repeated benzodiazepine administration. In contrast, the extrasynaptic $GABA_A$ receptor remains responsive to GNX during seizure events and does not desensitize with repeat GNX treatment. GNX blocks seizures in a broad range of experimental epilepsies and is now in clinical development for the treatment of various epileptic conditions. In recent preclinical studies we've demonstrated that IV administered ganaxolone blocked seizures in a clinically translatable model of benzodiazepine resistant status epilepticus (SE). The current studies were conducted to expand those findings by assessing the effects of the combination of IV administered GNX and diazepam on experimental SE. SE was induced by administration of lithium chloride and pilocarpine to Sprague-Dawley rats. Seizure response was measured by electroencephalographic recordings through pre-implanted cortical electrodes. Diazepam and GNX were administered alone or in combination via IV bolus administration 15 min after SE onset. The pilocarpine-induced seizures were sustained for approximately 6 hrs and were resistant to diazepam up to a dose-level of 10 mg/kg. In a previous study GNX at dose-levels of >12 mg/kg produced a complete and durable block of SE whereas lower doses were not protective. In the current study, diazepam at 5 mg/kg in combination with GNX administered at subtherapeutic dose-levels of 3 or 6 mg/kg caused a partial and complete block of SE,

respectively. The pharmacokinetics of GNX and diazepam were identical when administered alone or in combination indicating that neither drug affected the pharmacokinetic disposition of the other and suggesting that this synergistic enhancement of anti-epileptic activity occurred at the level of the $GABA_A$ receptor. Further, these data have clinical implications in the treatment of SE when GNX is to be administered to patients who are or have been treated with benzodiazepines.

Title: Using high-throughput screening to predict novel antiseizure interventions

Authors: ***A. MOUSAVI NIK**, S. HULSIZER, I. PESSAH;
Univ. of California Davis, Davis, CA

Abstract: Tetramethylenedisulfotetramine (TETS) is a potent convulsant that increases electrical activity and spontaneous Ca^{2+} oscillations in neural networks by blocking $GABA_A$ receptors. Acute exposure to TETS (≥ 3 μM) significantly increases spontaneous Ca^{2+} oscillations (SCO) amplitude and decreases SCO frequency. Since neurosteroids and benzodiazepines are positive allosteric modulators (PAMs) distinct mechanisms at $GABA_A$ receptors, we tested 27 neurosteroids and 2 benzodiazepines singly or in combination for their potency to mitigate TETS-triggered SCO abnormalities. SCOs were measured *in vitro* using mouse hippocampal neuronal cultures loaded with Flo-4 using FLIPR Tetra (Molecular Devices) high-throughput fluorescent cellular screening system. The SCOs were measured from mature networks at 12-15 days in vitro. Acute challenge to TETS rapidly altered the amplitude and frequency of SCOs and neurosteroids and benzodiazepines were tested for their ability to normalize SCO patterns. The

most potent candidates/combinations were also tested for their ability to normalize TES-triggered neuronal network electrical activity using multi-well micro electrode array (MEA, Axion) technology. Our results suggested that of 27 neurosteroids screened in hippocampal neuronal cultures, allopregnanolone, ganaxolone and XJ-42 are the most potent, and more potent than the benzodiazepines midazolam and diazepam. The combination of neurosteroids and benzodiazepines at low concentrations significantly reversed the effect of TETS and proved synergistic. High throughput screening using FLIPR and MEA to monitor SCO patters and Ca^{2+} dynamics is a potentially useful approach for identifying novel therapeutic agents that mitigate hallmarks of seizurogenic activity in vitro.

Title: Title: The MED64-Quad II system increases throughput for studies of antiepileptic drug targets with *In vitro* MEA pharmacology on acute brain slices

Authors: S. YASUOKA[1], R. ARANT[2], *G. CHENG[2];
[1]Alpha MED Scientific Inc., Osaka, Japan; [2]Alpha Med. Scientific Inc./ Automate Scientific Inc, Berkeley, CA

Abstract: Micro-electrode arrays (MEAs) have been widely utilized to measure neuronal activities *in vitro*. The MEA technology offers many unique advantages to investigate neuronal circuitry, interaction and models of learning and memory, development, aging, disease and neurotoxicity. While several high-throughput platforms have been utilized for drug screening with cultured cell applications in recent years, there have been limited platforms designed for acute and culture slice applications. Here we present the capabilities of the MED64-Quad II system, a novel medium-throughput MEA designed specifically for acute or cultured slice applications. Recordings were made from acute hippocampal slices from 6-8 week old male ICR strain mice and the extracellular signals were obtained at 16 electrodes per slice (4 slices recorded simultaneously) or 64 electrodes per slice with MED64-basic system. Spontaneous spikes were recorded with 4 slices simultaneously using the MED64-Quad II System. On a given experiment of 16 or 64 electrodes recording, spontaneous firing were recorded from hippocampal and entorhinal cortex. The firing frequency per channel and the number of synchronized bursts were analyzed. Pharmacological agents NMDA, bicuculline, kainate, AP5,

CNQX, PTZ (pentylenetetrazole), and VPA (sodium valproate) were tested on the slices using MED64 system. The synchronized bursts were seen following bath perfusion of drugs. Antiepileptic drugs reduced the burst discharges. The results of this study indicated that the MED64-Quad II and Basic system increases throughput while maintaining high sensitivity to detect spontaneous spiking signals. It is a useful tool for drug discovery, target validation, compound screening for antiepileptic drug targets and pharmacological studies in acute brain slice applications *in vitro*.

Title: Neuroactive Steroids exhibit synergistic interactions with barbiturates at the $GABA_A$ receptor *In vitro* and this impacts on activity in an animal model of seizure

Authors: *M. A. ACKLEY, G. M. BELFORT, R. S. HAMMOND, M. C. QUIRK, G. MARTINEZ-BOTELLA, F. G. SALITURO, A. J. ROBICHAUD, J. J. DOHERTY;
SAGE Therapeut., Cambridge, MA

Abstract: Allopregnanolone and certain other second generation neuroactive steroids (NAS) are positive allosteric modulators of $GABA_A$ receptors, and are currently being studied for the treatment of seizure disorders such as super refractory status epilepticus and orphan genetic epilepsies. These compounds are believed to bind to one or more sites that are distinct from other classical modulators of $GABA_A$ receptors and as such are capable of modulating a broader range of subunit combinations than for example, benzodiazepines. We therefor sought to evaluate whether NAS could interact with other modulators at the level of the $GABA_A$ receptor and whether this interaction could amplify the activity of NAS in aborting seizures *in vivo*.
Whole cell patch clamp recordings were made from cells that heterologously expressed $GABA_A$ receptors. Allopregnanolone produced a concentration-dependent potentiation of GABA currents in cells expressing recombinant $\alpha_4\beta_3\delta$ subunits, which was 16,000-fold more potent than the modulation by pentobarbital. In the presence of a low concentration of pentobarbital the concentration-response curve of allopregnanolone was enhanced with an increase in the E_{max}, indicating a potential synergistic interaction. Construction of isobolographs confirmed that the interaction between allopregnanolone and pentobarbital was indeed synergistic.
To understand if this synergistic interaction would have a physiological impact, we assessed the

ability of NAS with or without phenobarbital to inhibit epileptiform discharges (ED) in brain slices. A synthetic NAS, SGE-516 inhibited ED in a concentration-dependent manner and in the presence of an inactive concentration of phenobarbital, the concentration-response curve was shifted to the left indicating an increased potency of SGE-516.
We next chose to assess whether NAS interacted with pentobarbital *in vivo*. Status epilepticus was induced in rats using lithium-pilocarpine and seizure activity was monitored using EEG. Allopregnanolone (0.3-15 mg/kg IV) reduced Spike Probability (SP), indicating a suppression of seizure activity. Plasma concentrations required to significantly reduce SP were in excess of 18 μM. When administered in the presence of a sub-active dose of pentobarbital (10mg/kg), the concentration of allopregnanolone required to significantly reduce SP, decreased 16-fold.
These data suggest that naturally occurring and synthetic NAS such as allopregnanolone and SGE-516 may interact with common modulators of $GABA_A$ receptors in a synergistic manner and support further study to determine if this interaction can result in an enhanced anti-convulsant potency *in vivo*.

Title: Partial activation of TrkB receptors corrects interneuronal calcium channel dysfunction and reduces epileptogenic activity in neocortical circuits following injury

Authors: ***F. GU**, I. PARADA, T. YANG, F. LONGO, D. PRINCE;
Neurol. & Neurolog. Sci., Stanford Univ., Stanford, CA

Abstract: Decreased GABAergic inhibition due to dysfunctional inhibitory interneurons plays an important role in posttraumatic epileptogenesis. We previously showed that reduced N-current Ca^{++} channel (N-channel) function in GABAergic terminals contributes to interneuronal abnormalities and neural circuit hyperexcitability in the partial neocortical isolation ("undercut" or "UC") model of cortical injury. Because of the known role of BDNF in development and maintenance of interneurons, we tested the hypothesis that chronic TrkB activation would correct N channel abnormalities and suppress neural circuit hyperexcitability in the UC model of posttraumatic epileptogenesis. PTX BD4-3 (BD), a partial agonist at the BDNF TrkB receptor, was injected in UC rats (50mg/kg, once a day, i.p.) for 7 days beginning on the day of injury. Immunocytochemistry and confocal microscopy were used to assess the density of N and P/Q channels in presynaptic GABAergic terminals. Whole cell patch clamp recordings of evoked inhibitory postsynaptic currents (eIPSCs) from layer V pyramidal cells, together with effects of bath-applied N and P/Q channel blockers ω-conotoxin and agatoxin were used to determine effects of BD on N and P/Q channel function, respectively. To determine whether BD can decrease injury-induced circuit hyperexcitability, we treated control and UC rats *in vivo* with 45mg/kg pentylenetetrazole (PTZ) i.p 10 days after 7 days of saline or BD treatment and compared the incidence of EEG and behavioral seizures between different groups. Results showed that 1) chronic BD treatment up-regulated both N- and P/Q channel-immunoreactivity in GABAergic terminals; 2) the reduction in eIPSC amplitude after either N channel or P/Q channel blockade was increased in BD-treated UC rats, indicating enhanced function of both N and P/Q channels in the interneurons of UC cortex; and 3) BD treatment reduced the susceptibility to PTZ-induced seizures in UC rats. Results suggest that chronic TrkB activation with a partial agonist could be a promising strategy to rescue the injury-induced calcium channel abnormalities in inhibitory presynaptic terminals, thereby improving interneuronal function and suppressing circuit hyperexcitability following cortical trauma.

Title: A critical developmental window for 17β-estradiol antiepileptogenic effect in a mouse model of x-linked infantile spasms

Authors: *M. SIEHR, R. LUCERO, J. LALONDE, J. NOEBELS;
Neurol., Baylor Col. of Med., Houston, TX

Abstract: X-linked Infantile Spasms Syndrome (ISSX) is a catastrophic childhood epilepsy disorder. There are few treatments available that effectively reduce motor spasms in infants, prevent epilepsy later in life and improve developmental outcomes in children with ISSX. A common genetic cause of ISSX is a triplet-repeat expansion mutation in the *Aristaless-related homeobox* (*ARX*) gene. Our lab generated a mouse model with this mutation and $Arx^{(GCG)10+7}$ mice recapitulate many phenotypic features of ISSX, including neonatal motor spasms and epilepsy. ARX is a crucial transcription factor for the development of cortical GABAergic interneurons and $Arx^{(GCG)10+7}$ mutant mice have significantly reduced numbers of cortical GABAergic interneuron subtypes. Recently, our lab demonstrated that a one-week treatment of 17beta-Estradiol (E2) (40ng/g/day) administered to neonatal (P3-10) mutant mice reduced spasms in neonates and seizures in adults. Interestingly, E2 treatment in neonatal mutants also restored numbers of GABAergic interneuron subtypes in adults. This effect was age-dependent, as treatment of adults (P33-40) with E2 had no effect on these phenotypes. These results indicate that only early administration of E2 may have an antiepileptogenic effect in the $Arx^{(GCG)10+7}$ model. In order to effectively translate this therapy to the clinic, we must further define this critical developmental window. In this work, we aimed to define the temporal boundary for effective E2 treatment by delaying treatment initiation from P3 until P7. Delaying E2 treatment until the second postnatal week (P7-13) had no effect on seizures or interictal spikes (a second measure of cortical hyperexcitability) in adult $Arx^{(GCG)10+7}$ mice. These results indicate that there is a critical developmental window for antiepileptogenic effect of E2 in the *Arx* model of ISSX. Little is understood about the molecular mechanism of the antiepileptogenic effects of E2 and the basis for the critical therapeutic window. As estrogen receptor beta (ERb) is expressed in developing interneurons, we began by exploring whether activation of this single estrogen receptor subtype is sufficient to reproduce the effect seen with E2. Selective activation of ERb using LY500307 (Eli Lily & Co.) at 200ng/g/day from P3-10 was sufficient to produce a partial antiepileptogenic effect in $Arx^{(GCG)10+7}$. Treatment with LY500307 significantly reduced seizures but not neonatal spasms or interictal spikes. Full effect may require activation of other ERs. We aim to further elucidate the cellular and molecular mechanisms underlying the antiepileptogenic and neuroprotective effects of E2 in the $Arx^{(GCG)10+7}$ model of ISSX.

Title: Valproic acid decreases the absence seizures in a myelin mutant taiep rat: A new animal model of epilepsy

Authors: *M. CORTES, Y. SILVA, J. R. EGUIBAR;
B. Univ. Autonoma de Puebla, Puebla, Mexico

Abstract: Taiep rat is a new model of absence seizures that showed an initial hypomyelination followed by a progressive demyelination of central nervous system. The phenotype is inherited in an autosomal recessive manner. In electroencephalographic 24 hours recordings taiep rats have cortical spike-wave discharges (SWD) with a peak in the theta band frequency at 6.5 Hz, and occurs spontaneously along 24h. In the present study, we analyzed the effects of oral administration of 300 mg/kg of valproic acid on absence seizures and evaluate them during continuous electrographic recordings along circadian cycle. The rats were maintained in experimental room with a 12/12 light-dark cycle with the lights on at 0700. Rats were free access to rodent pellets and purified water. Rats were anesthetized by i.p. injection of ketamine-xylazine mixture and placed in a stereotaxic apparatus (Kopft). Three stainless steel screws were implanted under aseptic conditions for electroencephalographic recordings, and a bipolar electrode in the CA1 field of the hippocampus and also Ni-chromium electrodes for electrooculogram and electromyography recordings. All signals were digitalized, filtered and stored in a hard disk of PC computer and analyzed using Harmonie software (Stellate). After valproic acid by oral administration in male taiep rats showed less frequency of SWD ($P<0.05$), and also a diminution in their mean duration ($P<0.05$). These effects lasted more than 8h suggesting that they are more sensible to this prototypical antiepileptic drug in a similar way as WAG/Rij and GAERS rats. In conclusion, taiep rats are a suitable model of absence seizure and also to test new antiabsence drugs.

Title: Acute effects of lacosamide on spasms in the multiple-hit rat model of infantile spasms

Authors: *O. SHANDRA[1], W. B. MOWREY[2], S. L. MOSHÉ[1,3,4], A. S. GALANOPOULOU[1,3]; [1]Saul R. Korey Dept. of Neurology, Lab. of Developmental Epilepsy, [2]Dept. of Epidemiology and Population Hlth., [3]Dominick P. Purpura Dept. of Neuroscience, Montefiore/Einstein Epilepsy Ctr., [4]Dept. of Pediatrics, Albert Einstein Col. of Med., Bronx, NY

Abstract: BACKGROUND: Infantile Spasms (IS) are age-specific epileptic seizures of West syndrome, associated with severe cognitive and neurodevelopmental deficits, high risk of early mortality and intractable epilepsy development. Outcomes might be partially improved by early cessation of spasms with effective therapy. We used a multiple-hit rat model to recreate medically refractory IS due to structural lesions and to identify new therapeutic agents for IS with rapid effect on spasms.
OBJECTIVE: Determine whether a single injection of an antiepileptic drug lacosamide, used for treatment of other types of seizures, can produce rapid cessation of spasms in the multiple-hit rat model of IS.
METHODS: To induce the spasms, male Sprague-Dawley rats received right intracerebral injections of doxorubicin and lipopolysaccharide on postnatal day (PN) 3 and intraperitoneal (i.p.) injection of p-chlorophenylalanine on PN5. Daily milestones of the rats were scored using a battery of neurodevelopmental tests. Intermittent video monitoring of the rats was done on PN4 (1 hour pre-drug injection and 5 hours post-drug injection) and on PN5 (2 two-hour sessions). Rats were sacrificed for histology on PN5 after last monitoring session. A single i.p. injection of lacosamide (10, 30 and 50 mg/kg) or vehicle was given after the onset of spasms on PN4 in a randomized, blinded, vehicle-controlled, dose-response study. A linear mixed model analysis of raw or normalized log-transformed spasm rates was used, considering the repeated observations on each individual animal. 12-15 rats per group were studied.

RESULTS: All tested doses of lacosamide, given as single injection after the onset of spasms, produced a rapid cessation of spasms within the first post-injection hour. Significant reduction of spasms was seen at the 4th hour (seen with the 30 and 50 mg/kg/i.p. dose) and 5th hour (seen with the 30mg/kg dose; borderline effect seen with the 50mg/kg i.p. dose). All doses were well tolerated. Neurodevelopmental outcomes were unaffected.
DISCUSSION: We provide proof-of-concept evidence that a single injection of lacosamide given after the onset of spasms can acutely suppress the spasms in the multiple-hit rat model of IS. The ongoing studies include the correlation of the efficacy of lacosamide with its pharmacokinetics and video-EEG recordings analysis. Our future goal is to test the effects of lacosamide on spasms, long-term neurodevelopmental, cognitive and epilepsy outcomes after repeat administration in the multiple-hit rat model of IS.

Title: Transcranial focal electrical stimulation via concentric ring electrodes in freely moving cats, antiepileptogenic and postictal effects

Authors: *A. VALDÉS-CRUZ[1], B. VILLASANA-SALAZAR[2], W. G. BESIO[3], V. M. MAGDALENO-MADRIGAL[2], D. MARTÍNEZ-VARGAS[2], S. ALMAZÁN-ALVARADO[2], R. FERNÁNDEZ-MAS[2];

Abstract: Temporal lobe epilepsy exhibits a high resistance to pharmacological treatments. Transcranial focal electrical stimulation (TFS) via tripolar concentric ring electrodes (TCRE) is a non-invasive experimental proposal to treat pharmacoresistant epilepsy. Thus the aim of our study was to investigate the effect of preventive- and responsive-TFS application via TCREs on

convulsive activity induced by electrical amygdaloid kindling (AK) model of TLE epileptogenesis, which consists in repeated and periodical electrical stimulations to limbic brain structures, leading progressively to the induction of an electroencephalographic afterdischarge. Therefore we investigated the effect of TFS on seizure activity by stimulating over the kindled area in cats. In addition, spectral power analysis of electrographic activity induced by TFS was also explored. Fifteen adult cats were implanted in both amygdalae (AM) and prefrontal cortices (PFC) and assigned to three experimental groups: Control, only received AK; preventive-TFS group in which a TCRE was placed over the vertex, TFS (300 Hz, 200 μs biphasic square pulses) was delivered for 40 minutes prior to AK. Responsive-TFS group, with the TCRE over the temporal bone ipsilateral to the kindled AM, TFS was administered for 2 minutes after the AK onset for 40 days, thereafter only AK was applied. Daily AK was applied (60 Hz, 1 ms monophasic square pulses for 1 s, 300-500 μA) until all animals reached kindling stage VI. Spectral power analysis was performed in frequency bands 1-4 Hz, 4-9 Hz, 10-14 Hz and 15-30 Hz on signals from both PFC and AM. Responsive-TFS inhibited the kindling development. This suppressive effect was long-lasting with the Responsive-TFS group remaining at the focal seizure stages for the next 20 days after the TFS cessation, and needed 80.0 ± 15.42 AK stimulations to reach stage VI. Preventive-TFS did not protect against epileptogenesis. Nonetheless, it produced a continued decrease in postictal spectral power. In conclusion TFS applied during seizures over the epileptogenic area may exhert a therapeutic effect against intractable epilepsy with the advantage of its non-invasive application.

Title: Effects of High- and Low-frequency stimulation of thalamic reticular nucleus on ptz-induced seizures in rats

Authors: *V. M. MAGDALENO-MADRIGAL, A. VALDÉS-CRUZ, D. MARTÍNEZ-VARGAZ, S. ALMAZÁN-ALVARADO, R. FERNÁNDEZ-MAS;

Abstract: The use of electrical stimulation therapy for epilepsy is currently being studied in experimental animals and patients. We have reported that the high-frequency stimulation (HFS) in the thalamic reticular nucleus (TRN) induced an anti-epileptogenic effect. Our study was designed to evaluate the effects of HFS and low-frequency stimulation (LFS) applied in the TRN on the expression of pentylenetetrazole-induced (PTZ) seizures. Experiments were performed using Wistar male rats, with electrodes stereotaxically implanted in the left TRN (AP -1.4mm, L 1.6mm, H 6.2mm). Epidural EEG recording screws were implanted in the prefrontal cortex for EEG recording. The rats were classified as follows: Control group, which received only PTZ injection; HFS+PTZ group, which received HFS prior to PTZ; LFS+PTZ, which received LFS prior to PTZ; PTZ+HFS, which received HFS after the PTZ injection; and PTZ+LFS, which received LFS after the PTZ injection. EEG recordings were obtained from the cortex and were evaluated to assess ictal behavior over 30 min. HFS and LFS in the TRN induced a significant decrease in seizure severity. Additionally, pre-treatment with HFS and LFS protected against death as a consequence of *status epilepticus*. The spike-wave complex frequency was modified in both HFS and LFS protocols. These data further highlight the role of TRN in mediating the expression of seizures and provides experimental support for the concept that this thalamic region may be a promising target for focal stimulation to treat intractable seizures in humans.

Title: Characteristics and consistency of seizure offset dynamics in humans

Authors: *D. N. CRISP[1], J. SCOTT[1], M. COOK[3], M. DUEMPELMANN[4], G. WORRELL[5], W. STACEY[2];
[1]Biomed. Engin., [2]Univ. of Michigan, Ann Arbor, MI; [3]Univ. of Melbourne, Melbourne, Australia; [4]Univ. of Freiburg, Freiburg, Germany; [5]Mayo Clin., Rochester, MN

Abstract: Our recent model of seizure dynamics showed that seizure offsets can be described by a limited set of four possible behaviors that are well characterized in bifurcation theory [1]. We investigated the prevalence of each of these bifurcations in a set of 85 patients from 4 different centers, and found that within the population the most common offset dynamics are logarithmic (75%) and constant (15%) scaling of interspike intervals (ISI). In this work, we examine the consistency of seizure dynamics within patients recorded over several months and explore the dynamics of very long seizures. We measured the ISI of 985 seizures in 13 patients. Each of the 13 patients has a distribution of both logarithmic and constant scaled seizures, all with nearly the same 80% prevalence of logarithmic dynamics. Several patients had distinct populations of seizures with different lengths [2], each displaying different parameter distributions. In contrast, we analyzed 50 long seizures (> 2 minutes), and found that they were predominantly characterized by constant ISI (80%). One episode of subclinical status epilepticus lasting almost 60 minutes was characterized by multiples episodes of waxing and waning ISI. This seizure displayed multiple bifurcations that transitioned into irregular spiking before restarting a different bifurcation. It also contained multiple brief episodes of constant ISI with zero variance, which were never seen in shorter seizures. Together, these findings indicate individual patients have similar prevalence of each bifurcation type as in the general population for normal seizures. In contrast, longer seizures tend to have different dynamics. These findings indicate that bifurcation theory is a valuable tool to describe human epilepsy.

Title: Comparing interictal discharges from intracranial EEG in patients with and without epilepsy

Authors: *B. N. LUNDSTROM, G. WORRELL, M. STEAD;
Mayo Clin., Rochester, MN

Abstract: Introduction: Approximately 1% of people have epilepsy and seizures reoccur in an unpredictable fashion leading to significant morbidity. While interictal epileptiform discharges (IEDs) recorded with EEG, such as spikes and sharp waves, provide localizing information about the seizure focus, they generally are not found to correlate with an increased seizure probability.

We recently described epilepsy patients for whom the rate of IEDs recorded by intracranial EEG (iEEG) appears to be correlated with long-term seizure probability. Thus, the rate of IEDs may have more clinical relevance when recorded by iEEG rather than scalp EEG. This raises the question to what extent typically defined IEDs are specifically associated with epilepsy. Here, we examine the rates of interictal transients detected using a validated automated detector for IEDs in patients who underwent iEEG monitoring due to intractable facial pain. **Methods:** Patients without a history of seizures underwent iEEG monitoring with subdural electrodes prior to placement of cortical stimulating electrodes for treatment of facial pain. Transient EEG events were detected as IEDs automatically in six 15-minute blocks using a previously validated method (Barkmeier et al.) in five electrodes per patient. These data were compared with iEEG data gathered from epilepsy patients in high and low seizure probability states (Lundstrom et al.). **Results:** Preliminary results from a total of 15 hours of data from two patients show an average discharge rate of 0.06 per second (SD 0.03). The mean rate in electrodes distant to the seizure focus in epileptic patients was 0.14 per second (SD 0.11). The mean rate in electrodes near the seizure focus was 0.61 per second (SD 0.07) prior to treatment and 0.08 per second (SD 0.07) following treatment. **Discussion:** Although the rate of IEDs is very low in scalp EEG recordings of patients without epilepsy, our results suggest that it may not be negligible in iEEG recordings. The rates of iEEG transients classified as IEDs using an automated detector in patients without epilepsy is comparable to IED rates of treated epileptic patients. This raises the possibility that at least some transient EEG fluctuations similar to IEDs in patients with epilepsy may occur in patients without epilepsy, and these waveforms are not specific to epileptic mechanisms at the cellular level. One explanation is that these findings relate to cortical injury and the impact of implanted subdural grids on cortex. **References:** Barkmeier, D. T. *et al. Clin. Neurophysiol.* 123**,** 1088-95 (2012). Lundstrom, B. N. *et al.* Chronic subthreshold cortical stimulation to treat focal epilepsy, submitted.

Title: Mechanisms of widespread cortical fMRI increases and decreases in absence seizures

Authors: *Y. CHEN[1], S. BRAUN[1], J. GUO[1], H. BLUMENFELD[1,2,3];
[1]Dept. of Neurol., [2]Dept. of Neurobio., [3]Dept. of Neurosurg., Yale Univ. Sch. of Med., New Haven, CT

Abstract: It is hoped that an extensive understanding of the neuronal activity changes during spike-and-wave discharge (SWD) might lead to improved treatment for absence seizures. Blood oxygen-level dependent (BOLD) fMRI signal change is not directly related to neuronal activity as measured by EEG. The physiological basis for early fMRI increases and sustained decreases remains unknown. A standard hemodynamic response function (HRF) is commonly used to relate electrical brain activity to the expected fMRI timecourse. An important question is whether the small fMRI increases before seizures and sustained decreases after absence seizures can be explained by any electrical activity pattern when using the standard HRF. We created a signal processing model of electrical activity by deconvolving the BOLD signal with the canonical HRF. Activated neural activity before seizures and deactivated neural activity after seizures suggest that if the canonical HRF is correct, then the small increases before seizures and decrease in BOLD fMRI signals following seizures can't be explained by electrical activity during the seizure alone. Also we customized the HRF by using ictal period boxcar neural activity model alone. We also evaluated that neural activity changes occur only during the period of SWD. The electrical activity is modeled with a simple boxcar representing EEG seizure. To fit the data, this approach yielded customized HRFs which were markedly different from the canonical HRF including small increases of the response function before and profound decreases after EEG seizure times. With further investigation it is hoped that the full pathophysiology of neuronal changes before, during and after SWD can be better understood to help guide future treatment.

[1]Neurol., [2]Neurology, Neurobiology, & Neurosurg., [3]Neurosci., [4]Neurosurg., Yale Univ. Sch. of Med., New Haven, CT

Abstract: Epileptic seizures can significantly limit the ability of affected individuals to lead normal lives, especially when loss of consciousness occurs. Often, epileptic individuals are restricted from driving until it can be shown that seizures are fully controlled. In the U.S. driving license issuance is dependent on people with epilepsy maintaining a seizure-free period. Consequently, physicians play an important role in determining whether or not the patient should be allowed to drive. However, decisions about driving can be difficult due to the lack of objective data available about patient driving performance during the ictal and post-ictal periods of clinical seizures. In addition the potentially important effects of subclinical epileptiform discharges on driving safety are not known. In this study, we analyze ictal and interictal driving data captured prospectively from a driving simulator in patients undergoing video/EEG monitoring in the epilepsy monitoring unit at Yale New Haven Hospital. Performance data is analyzed with attention to ictal and interictal periods of play. A total of 33 seizures in 20 patients were analyzed, along with 143 subclinical epileptiform discharges in 9 patients. Baseline was defined as interictal driving performance and was compared to ictal driving performance through quantitative analysis of car velocity, steering wheel movement, application of the brake pedal and crash occurrence during the ictal and postictal periods as well as during subclinical epileptiform discharges. We found variable impairment both during seizure/postictal periods as well as during subclinical epileptiform discharges with some showing obvious impairment and others no change in driving performance. In ongoing work we hope to expand upon our current analysis of performance variables as well as determine whether specific seizure types or localizations present a greater driving risk, with the goal of providing improved guidance to physicians and patients with epilepsy.

Title: Frontal lobe seizures and impaired consciousness: intracranial eeg markers.

Authors: *R. GEBRE[1], M. DHAKAR[1], E. GROVER[1], I. QURAISHI[1], E. STERNBERG[1], I. GEORGE[1], A. SIVARAJU[1], J. BONITO[1], H. ZAVERI[1], L. GOBER[1], S. AHAMMAD[1], S. GHOSHAL[1], L. HIRSCH[1], D. D. SPENCER[2], J. L. GERRARD[2], H. BLUMENFELD[1,2,3]; [1]Dept. of Neurol., [2]Dept. of Neurosurg., [3]Dept. of Neurosci., Yale Sch. of Med., New Haven, CT

Abstract: Loss of consciousness is an important morbidity associated with epileptic seizures, and understanding how altered consciousness occurs could have impact on future therapies. Consciousness includes multiple levels of input and output that maintain alertness, attentiveness, and awareness of both self and the environment. Previous work from our laboratory using SPECT imaging and intracranial EEG analysis of temporal lobe seizures has supported the network inhibition hypothesis. This states that impaired consciousness in temporal lobe epilepsy involves activation of the temporal lobe leading to abnormal activity in the thalamus and brainstem subcortical arousal systems. These changes lead to the depressed function in the frontal and parietal association cortices and impaired consciousness. Research on the mechanisms of loss of consciousness in frontal lobe epilepsy is not yet as well defined. We initially examined the intracranial EEG in 9 focal frontal seizures from 6 patients that had impaired consciousness and noted that there was a common ictal pattern of widespread low voltage fast activity. We hypothesized that widespread low voltage fast activity may play a role in loss of consciousness in patients with frontal lobe seizures. To further investigate this hypothesis we obtained a larger cohort of 91 patients from the Yale epilepsy surgery program. We then included patients that had intracranial studies that found a frontal lobe onset, and excluded seizures with no meaningful behavioral interaction and also eliminated seizures that secondarily generalized. This led to a final cohort of 16 patients who were recorded from 2004-2015 and 50 seizures. In ongoing analyses, behavioral responsiveness during the ictal period will be scored while being blinded to the EEG recordings. Likewise, intracranial EEG recordings will be scored while being blinded to the videos of the seizure behaviors. These investigations should enable us to determine whether widespread low voltage fast activity or a different mechanism may cause widespread altered brain function and impaired consciousness in frontal lobe seizures.

Title: Synergism of cross-frequency coupling and phase synchrony in epileptic focus localization: an iEEG study

Authors: *T. NÁNÁSI[1,2], B. FILE[3], L. ERőSS[1], L. ENTZ[1], D. FABÓ[1], I. ULBERT[2,3];

Abstract: Background: Pharmacologically intractable epilepsy is a neurological disorder that has enormous impact on the quality of life of the patients. The therapeutic workflow involves intracranial electroencephalography (iEEG) recordings and surgical removal of the resection site (RS), which ideally overlaps with the epileptogenic zone (EZ). Determining the EZ is therefore a critical step. Clinical EZ detection relies extensively on peri-ictal recordings, which have to be collected in sufficient number and quality, usually resulting in more than one week of hospitalization with drug withdrawal and therefore poses heavy burden for the patients.
Methods: We used previously acquired clinical and subdural grid iEEG data of five patients suffering from drug resistant focal epilepsy. Electrode positions were reconstructed from preoperative MRI, and post-operative CT scans. Four 3 minute long segments of recordings free from any obvious epileptic activity with at least 1 hour of temporal separation from actual seizures were analyzed for each patient. The patients were sleeping during the acquisition. After band-pass filtering, Phase Amplitude Coupling (PAC) and Phase Lag Index (PLI) values were calculated and phase-synchronized phase-amplitude coupling constellations (PoP) were considered. Also, a heuristic approximation of spectral entropy (DASE) was assessed. The dimensionalities of the measurements were reduced using the node strength parameter of the resulting graphs, and then those per-electrode values were evaluated for EZ localization potential.
Results: Node strength maps delivered from the novel measurements (PoP and its combination with DASE) showed maximum values and higher averages inside the RS in the case of the four successful surgeries, whereas in the case of the patient with residual seizures the delivered maximum values and higher averages pointed outside the clinically applied RS.
Conclusions: In this pilot study we demonstrated the potential usefulness of phase-synchronized

phase-amplitude coupling constellations as a hybrid construct from well-established PAC and PLI coupling measurements in automatized EZ localization. Also, we introduce a heuristic approximation of spectral entropy which can further improve the specificity of EZ detection. Our analysis works on seizure-free sleep iEEG data abundant in a typical clinical setting and aside from the initial frequency band definitions operates in a threshold-free manner.

Title: Ripples show increased phase-amplitude coupling in mesial temporal lobe epilepsy seizure onset zones

Authors: *S. A. WEISS[1], I. OROSZ[2], S. MOY[3], L. WEI[3], M. VAN'T KLOOSTER[4], R. T. KNIGHT[5], R. F. HELFRICH[5], R. M. HARPER[3], A. BRAGIN[3], I. FRIED[3], J. ENGEL, Jr.[3], R. STABA[3];

Abstract: High frequency oscillations (HFO, 80-150 Hz; “ripples”) accompany learning and memory processes, but are also an epileptogenic biomarker. Differences between normal and pathological ripples are unclear, but we hypothesized that pathological events exhibit increased coupling between low-frequency EEG phase and ripple amplitude. We examined ripple phase-amplitude coupling (PAC) during inter-ictal intracranial depth macroelectrode recordings from 11 patients with mesial temporal lobe epilepsy using a Hilbert detector; PAC was determined by 1) computer-aided visual inspection of iEEG and ripple band, 2) identifying the modulating signal using oscillation-triggered coupling (OTC) measures, and 3) measuring PAC using a phasor transform and correlating the resulting coupling strength and phasor rate with the seizure onset zone (SOZ). Visual inspection of the iEEG and the modulating signal using OTC methods revealed two forms of PAC; type-I, coupling between inter-ictal discharge phase and ripple amplitude, and type-II, coupling between delta or theta oscillation phase and ripple amplitude. PAC-I ripples were larger amplitude and lower in frequency compared to PAC-II ripples. Type-I and type-II PAC coupling strength and rate were both increased in the SOZ. Ripple and phase-locked ripple phasor rates exhibited an 82%, and 87.7% precision for the SOZ, respectively. The SOZ rate ratio, comparing mean event rates in SOZ and non-SOZ, for phase locked ripple phasors increased across all 11 patients, relative to the ripple SOZ rate ratio. Phase-locking strength also correlated with likelihood of electrode placement in the SOZ. These results suggest that pathological ripples are generated by two distinct mechanisms distinguished by increased PAC magnitude.

Title: An algorithmic adjunct to visual inspection: using an Empirical Mode Decomposition based algorithm to detect seizures

Authors: *K. R. ASHMONT[1], J. KERRIGAN[2,3], M. TROESTER[2,3,4], R. JARRAR[2], S. HELMS TILLERY[5], P. ADELSON[2,5,3], B. GREGER[5];

Abstract: Objective: Visual inspection of electrocorticography (ECoG) data has remained the seizure identification and localization method of choice for over 65 years. Visual inspection, however, is subjective and lacks specificity and sensitivity. Computational algorithms can quickly and objectively find signal characteristics that may not be detectable with visual inspection. Many seizure detection algorithms assume stationarity or linearity, making them inappropriate for the analysis of biological data. Empirical mode decomposition (EMD) does not require linearity or stationarity and is data driven. We propose the use of EMD as a seizure detection tool to supplement the visual review process.
Methods: EMD is an adaptive sifting algorithm that iteratively breaks complex waveform data into component waveforms, called intrinsic mode functions (IMF). The number of IMFs produced during the decomposition process is indicative of the complexity of the original waveform, with respect to frequency and amplitude. An EMD based algorithm was developed and tested on data from eight patients undergoing ECoG monitoring for refractory epilepsy. The recorded data were broken down into 136 ten-minute long clips. There were 68 seizure clips that were centered on a clinically determined seizure onset times, and 68 associated non-seizure clips. Prior to applying EMD, the signals for each grid were common average re-referenced (CAR). The algorithm was windowed through the data clips in 5 s windows with a 3 s step size. Two thresholds were established, one for each individual electrode and one for all electrodes used in each patient. Electrographic events were identified by considering changes in the number of IMFs generated for each individual electrode. Potential seizures were marked based on patterns

in increases in the number of IMFs across the population of all electrodes in a given clip.
Results: Analysis is ongoing. Current methods produced an algorithm sensitivity ranging from 100.00% to 40.00% across patients, when compared to seizures marked by visual inspection. The mean false positive rate is 1.24 detections/hr. There are a total of 14 false negative detections, 12 of which occurred when there was a deep focus.
Conclusions: The results suggest that a biological data driven algorithm could serve as a useful tool to objectively identify changes in cortical activity associated with seizures. However, detection algorithms may need to be adapted to different electrode types or particular neural structures. A process based on an appropriate algorithm could objectify and standardize the reviews across centers, leading to improved patient care.

Title: Disruption of resting state networks by section of the corpus callosum in humans

Authors: *J. L. ROLAND[1], A. Z. SNYDER[2], C. D. HACKER[3], E. C. LEUTHARDT[1], M. D. SMYTH[1];

Abstract: Functionally related areas of cerebral cortex maintain correlated time signals in blood oxygen level dependent (BOLD) magnetic resonance imaging (MRI). These well-organized areas constitute networks that are identified in resting state functional connectivity MRI (rsfcMRI) analysis. To advance our understanding of these cerebral networks we studied individuals undergoing section of the corpus callosum for medically refractory epilepsy. Our cohort consists of twenty-six pediatric patients who underwent rsfcMRI before and after undergoing transection of either the anterior two-thirds (N = 7) or complete (N = 19) corpus callosum for medically refractory epilepsy. Our results show canonical networks, with bilateral coherence before intervention, are disrupted immediately after callosotomy. Ipsilateral signal coherence is maintained bilaterally. This is a highly unique cohort of surgically lesioned callosotomy patients with rsfcMRI analysis pre- and immediately post-intervention. These data

implicate the corpus callosum as a means for network coherence via cortico-cortical communication opposed to thalamo-cortical modulation of resting state networks.

Title: Association between white matter changes and cognitive deficits in patients with temporal lobe epilepsy

Authors: *R. RODRÍGUEZ CRUCES, V. CAMACHO, L. CONCHA;
Inst. of Neurobio., Natl. Autonomous Univ. of Mexico, Queretaro, Mexico

Abstract: Temporal lobe epilepsy (TLE) is associated with white matter (WM) spread damage that extends beyond the epileptic focus (Otte el al; Epilepsia 2012). Furthermore, TLE patients also present cognitive impairments, which are related to structural changes through the brain (Dabbs et al; Epilepsy & Behavior 2009). Given that most cognitive abilities require an activation of several brain regions altogether, it is likely that the network abnormalities seen in TLE are responsible for cognitive problems.Our goal was to evaluate white matter structures in TLE patients, and to search for correlations between diffusion parameters of these structures and neuropsychological performance.
We included 18 Left TLE patients (L-TLE), 12 Right TLE (R-TLE) and 24 controls paired by

age, gender and years of studies. Images were acquired using a 3T scanner. Diffusion weighted images (DWI) were acquired with a resolution of 2x2x2 mm^3, 60 different diffusion gradient directions and one non-DWI volume.DWI where pre-processed and a diffusion tensor (DTI) model was fitted in order to obtain fraction anisotropy (FA) maps. The JHU-WM template was registered to the FA map to obtain 43 regions of interest (ROI) of the main WM fascicles. All subjects underwent full WAIS-IV and WMS-IV assessment. Each WM ROI was correlated with neuropsychological measures with an ANCOVA model per group. Statistical significance was defined as $p < 0.05$, corrected for multiple comparisons.
There were no significant differences of demographic variables between groups; neither between epilepsy groups in terms of age of seizure onset or number of anti-epileptic drugs. With respect to controls, R-TLE had significant differences in all cognitive areas evaluated ($p < 0.05$) while L-TLE only showed differences in 4 cognitive domains. Five regions of white matter showed a significant interaction with the group factor, and all of them showed a clear positive correlation only in the L-TLE group.
We found more extension of WM abnormalities and cognitive impairment in diverse neuropsychological scales in R-TLE group, as compared L-TLE.In both TLE groups the FA reduction was observed in associative fascicles such as uncinate and corpus callosum.
Conclusion: we found strong evidence of structural WM abnormalities that correlate with neuropsychological assessments in TLE patients. The spread WM alteration leads to a disrupted communication between different cerebral areas and therefore it impacts in the cognitive performance. The relation of structure with a specific cognitive performance helps to understand how chronic epilepsy spreads through the brain and it aids to get an accurate personal diagnosis and treatment.

Title: A prospective study of the prevalence of cell-surface neuronal autoantibodies in adult patients with recent-onset epilepsies of unknown aetiology

Authors: ***T. C. MOLONEY**[1,2], S. R. IRANI[2], J. ADCOCK[2], A. SEN[2], P. WATERS[2], A. VINCENT[2], B. LANG[2];

[1]Med. Physics and Physiol., Royal Col. of Surgeons, Ireland, Dublin, Ireland; [2]Nuffield Dept. of Clin. Neurosciences, Univ. of Oxford, Oxford, United Kingdom

Abstract: Background: The discovery of pathogenic autoantibodies, targeting neuronal surface proteins, has led to the concept of antibody-mediated diseases of the CNS. Various studies have found autoantibodies in approximately 10 % of patients with epilepsy, particularly in focal epilepsies of unknown cause. However, a formal study limiting patients to those with a recent diagnosis of focal epilepsy and search for novel cell-surface antigens needs to be performed. **Methods:** Two hundred and twenty four adults (113 female/111 male; age range 18-91) with newly-diagnosed focal epilepsies (<12 months of onset) were prospectively recruited from the Thames Valley region, United Kingdom. Participants' sera were tested for antibodies to glutamic acid decarboxylase (GAD), the voltage-gated potassium channel (VGKC)-complex and associated proteins, LGI1, CASPR2 and contactin-2, dipeptidyl-peptidase-like protein 6 (DPPX) and to the NMDA, AMPA, $GABA_B$, $GABA_A$ and glycine receptors. In addition, to observe novel surface antibodies, sera were tested for IgG binding to the surface of cultured neurons. **Findings:** Positive antibody titres were detected in 35 of 224 patients. Twenty-one of the positive samples had antibodies to the voltage-gated potassium channel-complex (VGKC-c); four patients were identified as being directed against known VGKC-c associated proteins LGI1 (n=2) and CASPR2 (n=2). A further two patients had additional autoantibodies to GAD or GABAb-receptors in conjunction with VGKC-c antibodies. Other antibodies detected included those to CASPR2 (n=2) and Tag1 (n=1) without associated VGKC-c antibodies, NMDAR (n=3), AMPAR (n=1), Glycine R (n=1) GABAaR (n=1) and GABAbR (n=1). Eleven sera showed positive IgG staining on rat hippocampal neurones and in 4 of these samples the antigen was not known. **Interpretation:** Detection of antibodies in 15.6 % of adult patients with new-diagnosed epilepsy, including 8.4 % with antibodies to neuronal surface antigens, adds substantially to previous studies that pointed to an antibody-mediated pathogenesis in a proportion of new-onset focal epilepsies in adults. Further research will be directed at improved understanding of clinico-serological correlation to enable identification of relevant clinical features that may better predict autoantibody-mediated epilepsy.

Title: Ictal-like HFOs during interictal periods can identify the seizure onset zone

Authors: *W. C. STACEY[1], K. R. MOON[2], A. O. HERO, III[2], S. V. GLISKE[2];
[1]Neurol., [2]Univ. of Michigan, Ann Arbor, MI

Abstract: High frequency oscillations (HFOs) are a biomarker of epileptic tissue, being developed to help guide resective surgery. One major challenge limiting clinical translation is that HFOs can occur due to both normal and epileptic processes. One potential method to distinguish between normal and epileptic HFOs is to compare “ictal-like” versus “interictal-like” HFOs. We hypothesize that healthy tissue can produce ictal-like HFOs, but that this should only occur when seizures have spread to that tissue. In contrast, we hypothesize that epileptic tissue may have “ictal-like” HFOs at any time. In order to classify HFOs, we used a validated automated algorithm in intracranial EEG recorded from 17 patients with refractory epilepsy. For each of the resulting >1.6 million HFO detections, 33 features were computed, including duration, power, line length, etc. The topology of the feature space was assessed using a non-parametric estimate of intrinsic dimension, and changes in the topology relative to time and channel were quantified using angular distance and a generalized Grassman-chordal distance. Linear discriminant analysis was used per channel to reduce the dimension, followed by a support vector machine (SVM) to classify the HFOs. This process was used to classify whether each HFO had ictal features. We then limited analysis to interictal periods and used the rate of "ictal-like" HFOs to identify seizure onset zone. This method was more accurate than using the rate of all HFOs, as is traditionally done. This demonstrates a novel, effective method to classify abnormal HFOs, which can have significant impact in their translation as epilepsy biomarkers.

Title: Interictal determination of the seizure onset zone and laterality of patients developing a cognitive task

Authors: *J. GONZALEZ-DAMIAN[1], P. E. SAUCEDO ALVARADO[2], M. MONTES DE OCA[2], A. L. VELASCO[2];
[1]Facultad de Medicina. Depto de Biología Celular y Tisular, Univ. Nacional Autónoma De México, Mexico DF, Mexico; [2]Clínica de Epilepsia, Hosp. Gen. de México, Ciudad de México, Mexico

Abstract: Objective To determine laterality and seizure onset zone, using High frequency Oscillations (HFO), of deep brain electroencephalographic recordings from resistant medial temporal lobe epilepsy patients that were developing an emotion recognition task. **Methodology** Transversal, observational and analytic study that includes the electroencephalographic recordings of patients (n = 8) in surgical protocol from the *Clínica de Epilepsia* of *Hospital General de México*, between the years of 2014 - 2016. All records were obtained from patients developing an emotion recognition task. Detection of HFO's was done using the short time energy method. The frequency spectrum was calculated for a time window of twenty seconds around each oscillation using the wavelet approximation. It was calculated the high frequency oscillations index (HFOI), the frequency and amplitude for each oscillation detected. The results were analyzed using descriptive statistics and one-way ANOVA. **Results** The number of HFO's is larger in the channels associated with the seizure onset zone ($p = 0.01$). The number of HFO's is significant different when compared between patients ($p = 0.05$). Average amplitude of HFO's was 100 mV. HFOI allow us to determine, in 83% of the cases, laterality and seizure onset zone as compared with the standard analysis. **Conclusions** HFOI could help to determine laterality and seizure onset zone in patients who develop a cognitive task. HFOI could help to reduce the electroencephalographic recording time of patients in surgical epilepsy protocol.

Abstract: Several studies indicate the endocanabinoids are involved in seizure activity. However, there is no information concerning signal transduction mechanisms downstream of the CB1 receptors in the human epileptic brain. In the present study, the CB1 receptor agonist-induced activation of the receptor/G protein complex was studied by measuring [^{35}S]guanosine´-γ-thiotriphosphate ([^{35}S]GTPγS) binding. The quantification of [^{35}S]GTPγS binding and its stimulation by selective receptor agonists represent an excellent experimental strategy to estimate if CB1 receptors are able to activate the nucleotide exchange on G_i/G_o proteins in the hippocampus and temporal neocortex of patients with temporal lobe epilepsy. The cerebral tissue was obtained from 24 patients during the epilepsy surgery. Their values were compared with values obtained of 6 subjects (autopsies) who died by accident and without history of neurological disease. The agonist-stimulated [^{35}S]GTPγS binding was evaluated in cell membranes. [^{35}S]GTPγS concentration assays revealed that [^{35}S]GTPγS binding stimulation by (R)-(+)-WIN 55,212+2, a CB1 agonist, was higher indicating augmented efficacy (Emax) in temporal neocortex (43.7%, $p<0.05$) versus autopsies (19.4%). When the same assay was conducted in hippocampus, the mean Emax value was not significantly different to autopsies (20.6%) versus patients (39.8%), indicating absence of CB1 receptor-mediated functional response in this brain area. The statistical analysis did not reveal significant differences in potency (EC_{50}) values in both brain areas. In conclusion, our present data obtained from patients with temporal lobe epilepsy provide strong evidence that CB1-induced signal transduction mechanisms downstream of these receptors are augmented in temporal neocortex, an effect non evident in hippocampus.

Title: Vagus nerve stimulation activates inhibitory neuronal network in human cerebral cortex

Authors: *T. MATSUO[1], K. KAWAI[2], K. USAMI[3];
[1]NTT Med. Ctr. Tokyo, Tokyo, Japan; [2]Neurosurg., Jichi medical university, Tochigi, Japan; [3]Neurosurg., Natl. Ctr. for Child Hlth. and Develop., Tokyo, Japan

Abstract: Introduction: Vagus nerve stimulation (VNS) is a surgical treatment for intractable epilepsy as a palliative therapy for of its less invasiveness and good seizure outcome. More than half patients can get 50% seizure reduction compared to preoperative seizure frequency. Although VNS is widely used for drug resistant epilepsy, little is known about therapeutic mechanism how electrical stimulation of the left cervical vagus nerve reduce the occurrence of epileptic seizure. Since epileptic seizure is caused by abnormal cortical activity, it can be presumed that there exit direct or indirect affection of VNS on the cerebral cortex. On the other hand, gamma coherence is thought to reflect the activity of inhibitory neuronal network. In this study, we recorded intracranial electroencephalography (iEEG) during VNS on/off period, and investigated the inter-cortical interaction.
Method: Four patients with intractable epilepsy who had already started VNS therapy participated in this study. iEEGs, direct recording of cortical activities, during VNS were recorded in acute or chronic phase. Two of 4 patients were performed bilateral craniotomy, whereas 2 patients were unilateral craniotomy. In total, data from 6 hemispheres were analyzed. Neuronal activities were recorded through grid arranged macro electrodes with a sampling rate of 2kHz, and recorded signals were analyzed offline. Eleven electrode sheets were placed on the surface of frontal or temporal lobe in both sides. Gamma coherence ranging 60 to 120 Hz between each electrode pair during VNS on/off period was calculated per electrode sheet.
Results: We found elevated gamma coherence in stimulating period compared to inter stimulating period. Averaged gamma coherence of stimulating period was significantly higher (0.21 ± 0.21) than inter stimulating period (0.19 ± 0.19) (paired t-test, $p = 0.03$). This trend was more prominent in right hemisphere (0.14 ± 0.09 and 0.13 ± 0.08; $p < 10^{-4}$).
Conclusion: Our results suggest a part of therapeutic mechanism of VNS that increased activity of inhibitory neuronal network elicited by VNS especially observed in right hemisphere consequently suppresses seizure occurrence.

Title: Loss of primary cilia in the oligodendrocyte lineage lineage in relation to myelination

Authors: A. SUBEDI, *J. L. FUCHS;
Biol. Sci., Univ. of North Texas, Denton, TX

Abstract: Primary cilia are non-motile, solitary sensory organelles present in most vertebrate cell types. Cilia-dependent signaling by sonic hedgehog contributes to proliferation, migration, and differentiation in the generation of oligodendrocytes. However, there are no reports of cilia in mature, myelinating oligodendrocytes. The present *in vivo* study systematically investigates the incidence of cilia in the mouse oligodendrocyte lineage during postnatal development, when myelination occurs. Primary cilia, identified by antibodies to adenylyl cyclase type 3 and Arl13b, were present in oligodendrocyte progenitor cells (OPCs), consistent with hedgehog-dependent generation of OPCs and oligodendrocytes. From P7 to P14, the percentage of $Olig2^{+}$ OPCs with a cilium decreased significantly, from 43% to 22% in cortex and from 36% to 15% in the corpus callosum. Mature, myelinating ligodendrocyte cells, identified by APC/CC1 expression, did not have cilia at any postnatal age, P4 through adultood. This observation suggests that cilia are lost in the lineage when cells gain the capacity to myelinate, and that oligodendrocytes are among the small minority of vertebrate cell types lacking primary cilia. Along with the loss of cilia, the centrosomal proteins γ-tubulin and pericentrin were both downregulated as oligodendrocytes gained APC/CC1. Myelin gene expression and timely myelination require enhanced Wnt/β-catenin signaling. Cilia can sequester β-catenin, and correspondingly, cilia loss should promote activity in the Wnt/β-catenin pathway. We propose that cilia loss in oligodendrocytes may promote the expression of myelin genes. Both OPCs and mature oligodendrocytes were Olig1+, but only those Olig1+ cells that lacked cilia co-expressed TCF3, a member TCF/LEF family which is associated with Wnt/β-catenin signaling. The results suggest that cells in the oligodendrocyte lineage lose primary cilia when becoming myelinating oligodendrocytes, and support the hypothesis that cilia loss serves to enhance the Wnt/β-catenin signaling required for the timely onset of myelination.

Title: Regulation of oligodendrocyte lineage cell function by the RXRγ nuclear receptor

Authors: *L. DI CANIO[1], A. GUZMÁN DE LA FUENTE[1], G. J. WAYNE[2], R. J. M. FRANKLIN[1];
[1]Univ. of Cambridge, Cambridge, United Kingdom; [2]GSK, Stevenage, United Kingdom

Abstract: Remyelination is an efficient process whereby oligodendrocyte progenitor cells (OPC) restore myelin by differentiating into oligodendrocytes (OLG). However, with increasing age in chronic demyelinating diseases such as multiple sclerosis, remyelination becomes less efficient, leaving axons vulnerable to degeneration. Understanding the process of OPC differentiation lies at the essence of developing endogenous therapeutic interventions by which remyelination can be enhanced.
We have identified RXRγ, a nuclear receptor (NR) able to regulate gene transcription, as an important positive regulator of OPC differentiation. RXRγ does so by forming heterodimers with other NRs and by further associating to co-regulators. The heterodimerisation of RXRγ to specific NRs appears to determine the stage of differentiation within the OLG lineage *in vitro*. In particular, Vitamin D Receptor, Peroxisome proliferator-activation receptor γ and Retinoic acid receptor β have been shown to be major binding partners, each one promoting a different and specific stage of OPC differentiation. However, RXRγ is able to heterodimerise with numerous other NRs as well as binding co-regulators to exert its function.
Using both Proximity Ligation Assay technology and a high-throughput screen of various NR agonists and antagonists, we are identifying the prevalent RXRγ binding partners in determining the OPC state. Binding partners with the strongest effect will be further explored in ageing OPCs as well as in an *ex vivo* remyelination paradigm. Concurrently, we are determining the genes controlled by RXRγ in the OLG lineage using ChIP-sequencing, which will shed light on the specific mechanism by which RXRγ controls progenitor cell fate.

Title: Comparing probes for zinc detection in developing and mature oligodendrocytes

Authors: *C. M. ELITT[1,2], K. PATEL[1], J. WANG[1], C. FAHRNI[3], P. ROSENBERG[1,2]; [1]Neurol., Boston Children's Hosp., Boston, MA; [2]F.M. Kirby Neurobio. Ctr. and Harvard Med. Sch., Boston, MA; [3]Sch. of Chem. and Biochem. and Petit Inst. for Bioengineering and Biosci., Georgia Inst. of Technol., Atlanta, GA

Abstract: Zinc is abundant in the central nervous system and required for proper function of a variety of enzymes, proteins and transcription factors. Increases in free ionic zinc (Zn^{2+}) play a critical role in neuronal and oligodendrocyte (OL) injury. Little is known about mechanisms of zinc regulation in developing or mature OLs and there is growing interest in imaging free ionic zinc to better understand the role of zinc signaling in normal cell function and development, as well as in cell death. We have previously shown that concentrations of free zinc are downregulated as OLs mature using Chromis-1, a novel Zn(II)-selective ratiometric fluorescent probe optimized for two-photon excitation fluorescence microscopy (TPEM) (Elitt et al., *SfN abstract* 481.08, 2015). The objective of the current study was to determine if other commonly used zinc probes such as Zinpyr-1 were comparable in detecting free ionic zinc in OLs. Mixed glia cultures were isolated from postnatal day 2 (P2) rat forebrains and grown for 10-17 days. Developing OLs were separated from microglia and astrocytes using selective detachment and then plated onto coverslips. Cells were maintained in the presence of platelet-derived growth factor (PDGF) and basic fibroblast growth factor (FGF) for 8 days prior to imaging. To produce mature OLs, PDGF and FGF were replaced by triiodothyronine (T3) and ciliary neurotrophic

factor (CNTF). Zinc imaging was performed using Zinpyr-1 (Cayman Chemical) or Chromis-1. Interestingly, baseline patterns of zinc localization were distinctly different with the two probes. Zinpyr-1 localized to discrete, focal structures within the cytoplasm while Chromis-1 was more uniformly detected in the entire cytoplasm with a finer pattern of punctate staining. Both probes appeared to be excluded from the nucleus. Previous studies in cell lines have suggested that Zinpyr-1 localizes to the Golgi (Burdette et al., 2001), while Chromis-1 is found in mitochondria, endoplasmic reticulum and endosomes. Further subcellular characterization in oligodendrocytes is necessary. It is important to identify the zinc pools labeled by each probe to select the optimal tool for specific indications. Future studies will compare the dynamic changes of these zinc probes under conditions of injury relevant to disorders and diseases targeting OLs.

Title: Transcription factor regulation by mTOR during oligodendrocyte differentiation

Authors: *I. M. ORNELAS, S. WAHL, L. KHANDKER, L. E. MCLANE, T. L. WOOD; Rutgers Univ., Newark, NJ

Abstract: Oligodendrocytes (OL) are generated from precursor cells that give rise to committed oligodendrocyte progenitor cells (OPCs), divide and migrate throughout the CNS. Differentiation of oligodendrocyte progenitor cells into mature oligodendrocytes requires extensive changes in gene expression. Several transcription factors play a role in the control of OL differentiation and such factors can be intrinsically and extrinsically regulated. We have shown that mTOR is critical for OL differentiation in vitro and in vivo (Tyler et al, 2009, 2011; Wahl et al., 2014). Here we furthered that analysis by investigating how mTOR controls the transcription factor machinery that is essential for the OPCs progression through the OL lineage. In the spinal cord of mice lacking mTOR in the oligodendrocyte lineage (CNP-Cre, floxed-mTOR) we found a significant increase in the mRNA levels of the inhibitor of DNA binding-2 (Id2). Conditional

knockout mice show an accumulation in early progenitors, PDGFRα+ cells, at the expense of O4+ cells in spinal cord at PND10. Moreover, Id2 mRNA expression is increased in sorted PDGFRα+ cells. Id2 is a negative regulator of transcription and differentiation in the OL lineage and is mainly regulated by BMP/Smad pathway (Samanta and Kessler, 2004). OPC cultures differentiated in the presence of rapamycin showed increased levels of phospho Smad1/5/8 compared to untreated control cells. Upon mTOR inhibition *in vitro* and *in vivo* we also observed a decrease in total levels of Sip1, which is a negative regulator of the Smads. Our preliminary results suggest that mTOR modulates Id2 expression through a complex regulation of the transcriptional machinery at its promoter, which is essential for OPCs to differentiate into mature oligodendrocyte.

Title: Regulation of oligodendrocyte progenitors through AMPA receptor signaling

Authors: *A. AGARWAL, L. CHAKRAVARTI, K. SPARKS, A. MENON, D. E. BERGLES; Dept. of Neurosci., Johns Hopkins Univ., Baltimore, MD

Abstract: Oligodendrocyte precursor cells (OPCs) express Ca2+ permeable AMPA receptors and form synapses with unmyelinated axons throughout the CNS. In vitro studies suggest that AMPA receptor signaling in OPCs may influence their proliferation, migration and differentiation. The primary obstacle in evaluating the function of AMPA receptors in OPCs in vivo is that they express the same complement of receptors that are present in neurons, precluding pharmacological manipulations. To overcome this limitation, we developed two conditional knock-in mouse lines in which AMPA receptor signaling can be modified in a cell specific manner. One line allows inhibition of AMPA receptor-mediated Ca2+ influx through expression of EGFP-tagged GluA2 subunits of AMPA receptors (EGFP-GluA2) and another line inhibits the formation of functional AMPA receptors through expression of EGFP-tagged dominant negative GluA2 subunits (EGFP-dnGluA2). These constructs were targeted to the ROSA26 locus to ensure widespread expression in developing or adult tissue. To evaluate

whether EGFP-GluA2 and EGFP-dnGluA2 were expressed at levels sufficient to modulate AMPA receptor function in OPCs, we bred Rosa26-lsl-EGFP-GluA2 and R26-lsl-EGFP-dnGluA2 mice to NG2-CreER/+ mice. Double transgenic offspring (NG2-GluA2 and NG2-dnGluA2) were injected with 4-hydroxytamoxifen (4HT) at various developmental stages and were analyzed between 2-20 weeks post-injections. Analysis of OPC behavior in these lines indicate that blocking AMPA receptor function in OPCs in vivo enhances their survival and rate of proliferation during development, whereas reduces their differentiation into oligodendrocytes (OL). A detailed 3D analysis revealed that OPCs lacking AMPA receptor function are morphologically less complex with stubby processes. To investigate the role of this signaling in OPC recruitment following demyelination, we induced a unilateral focal demyelination in the corpus callosum of mutant and control mice by injecting 1.0% Lysolecithin; and mice were analyzed two weeks post-injection. The number of OPCs expressing EGFP-dnGluA2 was significantly enhanced in the demyelinated lesion. Subsequent genetic fate tracing experiments revealed that in lesions, blocking AMPA receptor function in OPCs enhances their potential to differentiate into OLs. Together, these selective manipulations of AMPA receptor signaling in OPCs indicate that this form of rapid neuron-glial signaling alters key aspects of OPCs behavior namely proliferation, and differentiation into OLs.

Title: *In vitro* pre-transplant patterning of forebrain and spinal cord oligodendrocyte fates from human pluripotent stem cells

Authors: *T. MAJOR[1,2], A. H. KUROPATNICKA[1], S. A. GOLDMAN[1,2];
[1]Univ. of Copenhagen, Kobenhavn N, Denmark; [2]Ctr. for Translational Neuromedicine, Univ. of Rochester Med. Ctr., Rochester, NY

Abstract: Oligodendrocyte progenitor cells (OPCs) derived from human pluripotent stem cells (hPSCs) may be useful cellular reagents for the cell-based treatment of inherited and acquired disorders of central myelin. However, the extent to which regional patterning might limit the integration and/or function of hPSC-derived OPCs is unclear. To obviate this issue, we have established new protocols for specifically instructing OPCs to forebrain and spinal cord fates. Here we present protocols for the differentiation of forebrain (anterior) and spinal cord (posterior) OPCs from hPSCs, each based on a modified version of the dual-SMAD inhibition method. Both experimental approaches recapitulate the key region-specific developmental and transcriptional milestones of embryonic oligodendrocyte development. Combined application of LDN-193189, SB43154 and Pumorphamine with the small molecule inhibitor XAV939 or Retionic Acid results in efficient specification of forebrain (Pax6/FoxG1) or alternatively spinal cord (Pax6/HoxB4) neural precursors (NPCs). Further cultivation of NPCs in glial differentiation media (Wang et al., Cell Stem Cell, 2013) potentiates proliferation and differentiation of OPCs. Characterization of the developmental stages of anterior and posterior OPCs was achieved by immunocytochemistry. Subsequent validation of the cell phenotypes was performed by microaaray profiling and qPCR analysis. Global transcriptome comparison of anterior and posterior OPCs expression profile showed the robust induction of oligodendrocyte specific genes (OLIG2, NKX2.2, SOX10, PDGFRalfa) as well significant expression of myelin-related genes (MAG, MBP). Forebrain identity was confirmed by enrichment for FOXG1, OTX1, EMX2 while the spinal cord phenotype was determined by the significant enrichment for HOX gene family members. Fluorescence activated cell sorting (FACS) targeting the oligodendrocyte sulfatide recognized by mAb O4 permitted the purification of the resultant cell pre-patterned oligodendrocyte populations, which were capable of efficient in vivo myelination in immunodeficient shiverer x rag2$^{-/-}$ mice. In addition to providing a readily scalable source of anterior and posterior OPCs suitable for region-specific transplantation, these protocols provide new opportunities for the developmental analysis and comparison of forebrain and spinal cord oligodendrogenesis. In addition, such regionally specified anterior and posterior OPCs may prove useful in modeling those immune and metabolic demyelinating disorders that preferentially target either the forebrain or spinal cord white matter.

Title: Oligodendrocyte precursor cells (OPCs) dynamics and Kir4.1 profile in ageing brain

Authors: *I. CHACON DE LA ROCHA, A. D. RIVERA, A. M. BUTT;
Univ. of Portsmouth, Portsmouth, United Kingdom

Abstract: Oligodendrocyte precursor cells (OPCs) are abundant in the mammalian central nervous system (CNS) during development and they persist in adult CNS where they produce oligodendrocytes, the myelin forming cells, throughout life. A unique feature of OPCs is that they contact synapses and nodes of Ranvier and are able to respond to synaptic signals due to the expression of different ion channels and neurotransmitter receptors. It is believed that this signalling from neurons could regulate the dynamics of OPCs and this may have an important role in myelin formation and remyelination, which it is essential for rapid communication and cognitive function. The causes of cognitive decline in normal ageing are complex. However, changes in OPCs and myelin loss in ageing brain had been reported. Here, we used Microarray to profile changes in genes expressed in the adult 3 months old and 18 months old mouse optic nerve. We identified Kir4.1, an inward rectifying potassium channel highly expressed in OPCs, as one of the most upregulated glial transcript affected in ageing. We are currently investigating whether this is related to white matter changes in ageing brain.

Abstract: In the mature central nervous system (CNS), oligodendrocytes provide support and insulation to axons thanks to the production of a myelin sheath. During their maturation to myelinating cells, oligodendroglial precursors (OPCs) follow a very precise differentiation program, which is finely orchestrated by transcription factors, epigenetic factors and microRNAs (miRNAs), a class of small non-coding RNAs involved in post-transcriptional regulation. Any alterations in this program can potentially contribute to dysregulated myelination, impaired remyelination and neurodegenerative conditions, as it happens in multiple sclerosis (MS).
Here, we identify a developmentally regulated miRNA as a new actor of oligodendroglial maturation, that, in the mammalian CNS regulates the expression of myelin genes by simultaneously acting on several of its already validated targets. In cultured OPCs, over-expression of this miRNA by mimic treatment impairs while its inhibition with an antago-miR stimulates oligodendroglial maturation. Moreover, we show that miRNA levels are abnormally high in the cerebrospinal fluid of MS patients bearing active demyelinating lesions, suggesting that its pathological upregulation may contribute to MS development, at least in part by blockade of OPC differentiation leading to impaired repair of demyelinated lesions.
Further studies will be necessary to validate this miRNA as a possible biomarker for different stages of MS, providing a previously unrecognized venue for medical interventions.

Title: Autophagy regulates myelin compaction in the final stages of CNS myelination

Authors: *A. N. BANKSTON[1,2], M. D. FORSTON[1,2,3], A. E. SMITH[1,2], R. M. HOWARD[1,2], S. R. WHITTEMORE[1,2];
[1]Kentucky Spinal Cord Injury Res. Ctr., [2]Dept. of Neurolog. Surgery, [3]Dept. of Anatom. Sci. and Neurobio., Univ. of Louisville, Louisville, KY

Abstract: Myelination is critical for fast action potential conduction in vertebrates, and lack of myelin causes severe neurological disorders. Development of myelinating oligodendrocytes (OL), the sole providers of central nervous system (CNS) myelin, from proliferating oligodendrocyte precursor cells (OPCs) requires migration to target axons and defined morphological changes prior to myelination. The mechanistic basis for tight control of process extension, axon ensheathment, myelin wrapping, and the removal of cytoplasm to form compact myelin remain largely unknown. Here, we present evidence that autophagy, the targeted isolation of cytoplasm and organelles by the double-membrane autophagosome for lysosomal degradation, regulates myelin formation in mature OL. A marked increase in autophagic activity coincides with OL differentiation, with OL processes having the greatest increase in autophagic flux. Multiple lines of evidence indicate that autophagosomes form in developing myelin sheathes before trafficking from myelin to the OL soma. Pharmacological autophagy inhibition blocked myelination, producing OL surrounded by many short processes. Conversely, autophagy stimulation enhanced myelination while reducing the overall number of OL processes. Mice with OL-specific genetic deletion of the essential autophagy gene Atg5 develop a rapid tremor and die around postnatal day 12. Further analysis revealed nearly complete loss of CNS OPCs and reduced myelination. Intriguingly, the surviving Atg5-null OL produced myelin wraps that failed to compact. Mass spectrometric analysis of autophagosomes purified from differentiating OL identified actin and 2',3'-cyclic-nucleotide 3'-phosphodiesterase, proteins shown by others to be involved in myelin compaction. These results implicate autophagy as a key regulator of OPC

survival initially and myelin compaction during the terminal stages of myelination. Autophagy may provide an attractive target to both promote OL survival and subsequent myelin repair after injury.

Title: Fibroblast Growth Factor Receptor 1 in a mouse model of demyelination

Authors: *K. M. SMITH[1], H. M. TORRES[2], J. C. COLLETTE[2];
[1]Univ. of Louisiana At Lafayette, Lafayette, LA; [2]Biol., Univ. of Louisiana at Lafayette, Lafayette, LA

Abstract: Fibroblast Growth Factor Receptor 1 (Fgfr1) is a receptor for various Fgf ligands, including Fgf2, and has been implicated in multiple roles of CNS development and maturation including hippocampal stem cell proliferation, cerebellar development, corpus callosum formation via genesis of glial midline structures, and oligodendrocyte development. Consistent with these findings, we observe the tgFgfr1-EGFP BAC transgenic line to be expressed in the CNS in regions that are congruent with previously published in situ hybridization studies including embryonic ventricular zone, hippocampus, midline glial cells, hypothalamus, and cerebellar Bergmann glia. We have also observe Fgfr1 expression in cell types that are consistent with the known roles of Fgfr1 in development including Hippocampal stem cells and DCX positive progenitors, pyramidal neurons of the Hippocampal CA region, a majority of astrocytes, and in Olig2+ oligodendrocytes and oligodendrocyte precursor cells. An important question that remains to be answered is whether this model for tracing Fgfr1 expression can be used to investigate changes in GFP levels that would match that of the endogenous FGFR1 promoter. Specifically, can manipulations known to increase or decrease FGFR1 mRNA expression be

detected as changes in GFP expression? The cuprizone model of demyelination is well-studied model for examining oligodendrocytes and their precursors during the process of remyelination. In the acute model of cuprizone demyelination, animals eating a chow with cuprizone (typically .2% cuprizone) for 6 weeks develop demyelination in the corpus callosum. Fgfr1 expression as detected by in situ hybridization has been reported to increase in the corpus callosum in this model. We have performed cuprizone demyelination studies in the tgFgfr1-EGFP BAC transgenic line, and will compare the GFP expression levels in the cortex, corpus callosum and hippocampus in cuprizone (.2%) treated animals and control chow treated animals. We will further examine whether upregulation occurs in oligodendroctyes, astrocytes, or both cell types. Future studies will also aim to examine changes associated with a chronic model of cuprizone demyelination.

Title: Investigating immune system activation following loss of the Quaking (QKI) RNA binding proteins using PLP-CreERT

Authors: *L. DARBELLI, S. RICHARD;
Lady Davis Inst. For Med. Res., Jewish Gen. Hospital, McGill Univ., Montreal, QC, Canada

Abstract: Objective: Recently, we established that the adult inducible loss of QUAKING (QKI) RNA binding proteins in myelinating cells using *PLP-CreERT* results in impaired mobility, thoracic kyphosis and death by 30 days post tamoxifen injection (Darbelli L et al, 2016, J. Neurosci 36:4106-20). Adult inducible removal of myelin genes does not normally lead to lethality with little to no immune system involvement. Therefore, we sought to investigate whether immune system activation might be contributing to the severity of the phenotype in QKI-deficient mice. **Methods:** C57BL/6 $QKI^{FL/FL;PLP\text{-}CreERT}$ inducible knockouts (iKO) and wild-type (WT) littermates were used in our study. Eight-week-old mice were injected with tamoxifen to induce recombination and monitored thereafter. We used Fluorescence activated cell sorting

(FACS) to assess immune system activation and T-cell infiltration in the spinal cord of mice. Immunostaining was used to assess microglia activation, macrophage and T cell infiltration. **Results:** FACS of microglia isolated from central nervous system (CNS) of WT and iKO mice has shown an increased MHC class II expression in the iKO mice indicating that those cells are activated. Moreover, quantitative RT-PCR has shown an increased expression of microglia activation markers including C1qA and CD68 in spinal cords of iKO compared to WT, as well as an increase in pro-inflammatory cytokines and chemokines such as IL-1β and Ccl2, respectively. FACS analysis has also shown a lack of double positive $CD4^+CD8^+$ T-cells in the thymus and an increase in $CD4^+$ and $CD8^+$ T-cells populations in the spleen, which we are currently investigating. **Conclusion:** Microglia represent the first line of defense in the CNS. Therefore, we conclude that there may be some tissue damage or myelin debris that activates the microglia. This in turn might lead to activation of adaptive immune system and recruitment of T-lymphocytes in the CNS that will exacerbate the damage and contribute to the observed lethality in iKO mice.

Title: DNA damage-associated loss of cortical oligodendrocytes in dementia and Alzheimer's disease

Authors: *K.-H. TSE, A. CHENG, F. MA, H. CHOW, K. HERRUP;
The Hong Kong Univ. of Sci. and Technol., Hong Kong, Hong Kong

Abstract: The loss of myelin is a well-recognized, but poorly studied pathology of the aging brain. We have found loss of myelin, associated with a significant reduction in the number of oligodendrocytes (OL), occurs early in the brains of the R1.40 transgenic mouse model of Alzheimer's disease (AD). To extend these observations to humans with cognitive decline, we examined the prefrontal cortex of subjects with AD or plaque-free dementia (DEM) as well as normal controls (NC) (n = 8 for each, age = 72.3 [55-86], female = 50%). Using Black Gold II staining we observed fine myelinated fibers in the gray matter of frontal cortex in normal controls, but not in either AD or DEM subjects. The disappearance of gray matter myelin was

accompanied by a reduction in OL density (Olig2-positive, $p < 0.01$). Using myelin regulatory factor (MyRF) as a measure, we found that the number of actively myelinating OLs was reduced, in gray matter ($p < 0.0001$), but not in white matter. In DEM and AD brains, we found that Olig2+ cells had evidence of increased DNA damage (enhanced nuclear γH2A.X and 8-oxoguanine) and cell death (cleaved caspase 3). Gene expression profiling revealed an upregulation of genes related to DNA repair (ATM, ERCC1, ERCC2), and downregulation of genes associated with differentiated myelin genes (OLIG2, MBP and PMP22) in both DEM and AD group relative to NC. Further analysis revealed an inverse correlation between ATM and ERCC expression and Olig2+ and MyRF+ cell density in all subjects (Pearson r = -0.48 to -0.72, $p < 0.05$). To test the hypothesis that the DNA damage is a cause rather than a consequence of these events, we examined ataxia telangiectasia mutated knockout mice (*Atm*$^{-/-}$). As in human AD and the R1.40 mouse, the density of MyRF+ OLs was significantly reduced in cortical gray matter, but not in corpus callosum of 3 month-old *Atm*$^{-/-}$ animals; myelin gene expression (*Mbp, Mag, Myrf,* and *Ng2*) was downregulated as early as 1 month of age. Intracortical myelin degeneration is an early pathology in the ageing brain that likely contributes to cognitive decline. The preferential loss of cortical OL in the gray matter, and its strong association with DNA damage, suggests that unrepaired genetic damage drives myelin loss in dementia. The similarity of our findings in AD and DEM suggests that myelin pathology in dementia is likely caused by amyloid-independent mechanisms.

Abstract: It is currently acknowledged that an ideal therapeutic intervention to decrease stroke-associated disability should comprise both neuroprotective and neurorestorative approaches aimed at implementing local spontaneous post-injury repair mechanisms (Zhang and Chopp, 2009 Lancet Neurol).
Recent data obtained by fate-mapping analysis using the conditional GPR17-iCreERT2xCAG-eGFP transgenic mice, showed that the subpopulation of adult oligodendrocyte progenitors (OPCs, also known as NG2-glia) expressing the GPR17 receptor represents "a reserve pool" of OPCs, that is maintained for repair purposes after brain damage, including ischemic stroke (Viganò et al., 2016 Glia).
Here, we aimed at i) providing a detailed analysis of the fate and behavior of cells expressing GPR17 at different times after Middle Cerebral Artery occlusion (MCAo) in GPR17-iCreERT2xCAG-eGFP mice, and ii) exploring the cross-talk between microglia, the CNS resident immune cells, and OPCs, by assessing how vesicles released extracellularly by microglia (EVs) influence OPC behavior.
Starting from 72h after MCAo, we observed that GPR17 expressing-OPCs actively respond to the ischemic insult by increasing their capability to proliferate. At the same time point, cells in the dorsal cortex regions close to the ischemic area are polarized and display more directional branch extension toward the site of damage, suggesting OPC recruitment toward the lesion area. Data collected at 8 weeks after MCAo showed that some recombined cells at the border of the ischemic lesion also stain for the mature marker GSTpi, indicating that only a fraction of cells, belonging to the GPR17-positive pool of NG2 glia, has differentiated into mature oligodendrocytes.
Of note, *in vitro* studies pointed out that EVs produced by M1 pro-inflammatory microglia hinder OPC proliferation. On the contrary, 48h exposure to EVs from either M1 or M2 pro-regenerative microglia (but not resting cells) promotes OPC maturation, with EVs from M2 cells displaying higher activity. Interestingly, this is accompanied by GPR17 downregulation. These data suggest that microglial derived EVs may contain signals able to influence OPC proliferation and trigger their terminal maturation. Thus, shedding light on the mechanisms by which microglia activation interferes with the regeneration potential of OPCs is important for developing effective therapeutic interventions to implement functional recovery after ischemic stroke.

Title: Glial disruptions in response to cerebral hypoperfusion in young adult and aged rats

Authors: E. T. CURFMAN[1], H. C. PARAISO[2], *R. D. SWEAZEY[3], F.-L. CHANG[1], I.-C. YU[1];
[1]Indiana Univ. Sch. of Medicine-Fort Wayne, Fort Wayne, IN; [2]Indiana University-Purdue Univ. Fort Wayne, Fort Wayne, IN; [3]Indiana Univ. Syst., Fort Wayne, IN

Abstract: Vascular dementia (VaD) accounts for up to 20% of age-related dementia and presents a significant care burden on elderly patients and their caregivers. This form of cognitive impairment results from cerebral hypoperfusion and presents as diffuse white matter abnormalities that increase in severity with age. Given the myelinating activity of oligodendrocytes and their susceptibility to oxidative stress, the importance of glial mediation between vascular dysfunction and cognitive impairment is increasingly being recognized. Glial cells respond uniquely to disruptions in cerebral blood flow (CBF) based on their cell-type and location within a hypoperfused region, and deep white matter tracts are particularly vulnerable to ischemic insults. One model for VaD in rats is produced by permanent bilateral common carotid artery occlusion (BCCAO), and previous research has examined its effects in 3 month old animals. Young animal studies are common and exhibit up to 70% reductions in CBF for 3 days post-occlusion. However, few studies have examined aged animals. Given that the clinical presentation of VaD is primarily in elderly patients, and that white matter abnormalities increase in severity with age, studies using aged rats are warranted. To address this, we investigated VaD in both young adult (4-6 month old) and aged (24 month old) SD rats after BCCAO. We present findings that even in cases where CBF compensates rapidly after BCCAO, glial cells undergo long-term changes in both young adult and aged groups. These changes include reduction of mature oligodendrocyte mRNA markers CNPase, myelin basic protein, and myelin associated glycoprotein at 2 weeks post-BCCAO. At 4 weeks post-BCCAO, significant disruptions in white matter tracts can be seen by luxol fast blue staining in both young adult and aged groups. Furthermore, increases in GFAP stain intensity between young adult and aged rats indicate age-related changes in the astrocyte population. In adult animals, an increase in GFAP-positive cells in the superior medial striatum adjacent to the lateral ventricle indicates region-specific astrocytic response to cerebral hypoperfusion. We conclude that BCCAO produces multiple disruptions of glial cell functions following cerebral hypoperfusion in aged animals.

Title: A stroke-specific oligodendrocyte progenitor cell transcriptome reveals novel genes impacting recovery after white matter stroke

Authors: ***D. J. DITULLIO**, E. G. SOZMEN, S. T. CARMICHAEL;
Interdepartmental Program for Neurosci., UCLA, Los Angeles, CA

Abstract: Stroke is the leading cause of adult disability. White matter stroke (WMS) comprises 25% of all stroke, yet no treatments exist to address its devastating effects. Death of oligodendrocytes and subsequent demyelination is a major pathologic mechanism in WMS, and normal regeneration of oligodendrocytes by their progenitor population (OPCs) is inhibited. This differentiation block is the primary focus of the current study, as increasing myelination by oligodendrocytes after WMS has been linked to functional improvement.

We have developed a stroke-specific OPC gene transcriptome that provides insight into potential mechanisms underlying the WMS-specific OPC differentiation block. OPCs were isolated from the peri-infarct white matter using laser capture microdissection at two time points following injury: 5 days after stroke at the peak of the proliferative response, and at 15 days after stroke, at the peak of differentiation. Rigorous bioinformatics analysis of the OPC stroke transcriptome using a combination of statistical significance values, fold change in expression, and relative expression intensity measures has led to the generation of a quantitative priority list of ten genes predicted to most significantly impact OPC differentiation.

These ten genes are the subject of the current studies. Each gene is investigated first using primary OPC cultures as a screening system. Each gene of interest is up- and down-regulated in isolation, and effect on OPC differentiation is analyzed using qPCR and morphology analysis. Using results from these primary OPC culture studies, genes have been prioritized by their propensity to promote OPC differentiation. The two genes that most significantly influence OPC differentiation are being manipulated in vivo in a mouse model of WMS. Overexpression of each

gene via lentiviral induction allows for direct analysis of OPC response in the peri-infarct region. Fate analysis and myelin basic protein expression levels in the corpus callosum are used to analyze white matter recovery after WMS in control and test animals. Follow-up studies will focus on uncovering the mechanisms by which these genes play a role in OPC differentiation and remyelination after white matter stroke, improving our understanding of the unique pathologies of white matter ischemia and uncovering new potential targets for treatment.

Title: Functional heterogeneity of oligodendrocyte progenitors in the central nervous system

Authors: *S. FÖRSTER[1], A. C. CRAWFORD[1], R. B. TRIPATHI[2], W. D. RICHARDSON[2], R. J. M. FRANKLIN[1];

Abstract: In the mouse embryonic forebrain oligodendrocyte progenitors (OPs) are generated in consecutive waves from distinct brain regions along a spatiotemporal gradient, with ventral OPs emerging before dorsal OPs. Although these different OP populations functionally compensate during development, they persist in the brain throughout life. To investigate whether ventrally and dorsally derived OPs fulfil different functions in the adult brain, dorsally derived OPs were ablated using a Sox10-driven diphtheria toxin A (DTA) mouse model. As dorsally derived OPs mainly populate the cerebral cortex, locomotor coordination after the ablation of dorsally derived OPs was assessed first. Mice ablated of dorsally derived OPs show significant impairment in locomotor coordination. These impairments are not due to a decrease in overall brain white matter content shown by magnetic resonance imaging. Assessing the differentiation capabilities of ventrally and dorsally derived oligodendrocyte lineage cells *in vivo* demonstrated that after an initial delay in differentiation of dorsally derived OPs early after birth, ventrally and dorsally derived OPs give rise to similar numbers of mature oligodendrocytes in the adult brain. Our results point towards a distinct role of ventrally and dorsally derived OPC in executing specific brain functions in the adult brain. A more detailed analysis of signalling pathways differentially regulated in ventrally and dorsally derived OPs, and myelin structures formed by

oligodendrocytes derived from the distinct OP populations will help to further uncover the underlying difference of the two developmentally distinct OP populations.

Title: Preferential axon-oligodendrocyte interactions at axon varicosities preceding initial myelin ensheathment

Authors: ***M. MARTELL**, B. B. DUXBURY, S. W. STEELE, A. G. TRUDEL, A. J. TREICHEL, J. H. HINES;
Winona State Univ., Winona, MN

Abstract: Oligodendrocytes, the myelinating cell type of the central nervous system, extend exploratory membranous processes that sample numerous axons before beginning the initial wrapping of axons. During this process, specific axons will be chosen for myelination while other axons will never be wrapped. Although the functions and importance of myelin have been well characterized, the mechanisms directing oligodendrocytes to initiate myelin ensheathment are poorly understood. The objective of this study is to determine how oligodendrocytes recognize and distinguish specific axonal types prior to initial wrapping. One possibility is that oligodendrocytes select specific axons based on axon diameter, whereby axons with higher caliber are preferentially selected. To examine the axon-glia interactions preceding myelination, we performed in vivo imaging using transgenic zebrafish reporters that mark myelin-fated axons and oligodendrocytes. Both before and during initial ensheathment, we observed significant variability in thickness along the length of single axons. In vivo time-lapse imaging showed that axon morphology is highly dynamic before and during initial wrapping. Axons possessed swelling points, also known as varicosities, that underwent brief and localized radial growth. A subset of axon varicosities were transient, turning over within seconds, while others remained stable for greater than two hours of time-lapse imaging. Importantly, varicosities showed

frequent and sustained co-localization with pre-myelinating oligodendrocyte membrane processes. Prior to initial axon wrapping, axon varicosities interacted with oligodendrocyte processes 89.9% of the time, whereas neighboring thin axon segments showed interactions only 13.5% of the time. After initial wrapping, local axon diameter was greater at sites of new myelin ensheathment, suggesting that efforts to myelinate or stabilize myelin sheaths may be influenced by axon varicosities. Altogether, our findings demonstrate new cellular interactions between axons and oligodendrocytes that may specify axonal domains for ensheathment and stabilize wrapping attempts to facilitate myelination.

Title: The role of neuronal activity in myelination, axon targeting and maintenance of specified cortical projection neuron populations

Authors: *K. KORRELL, A. HOERDER-SUABEDISSEN, Z. MOLNÁR;
Oxford Univ., Oxford, United Kingdom

Abstract: Myelin in the central nervous system is produced by oligodendrocytes to ensure fast saltatory conduction of action potentials. Myelination is dependent on neuronal activity but the underlying mechanism is not yet completely understood. Because myelination has been implicated in many neuronal diseases (multiple sclerosis, schizophrenia) it is important to understand the underlying basics. To do so, neurotransmission will be suppressed in selected populations of cortical Layer V and VI projection neurons to determine how neuronal activity influences myelination. The fusion of neurotransmitter containing vesicles is mediated amongst others by the SNAP25 protein. To inhibit regulated neurotransmitter release Nrsr1 (for Layer VI) and Rbp4 (for Layer V) conditional Snap25 KO mice are bred on a floxed-stop-tdTomato background such that all silenced cells are tdTomato-labelled. The onset of myelination was established by assessing immunoreactivity for myelin basic protein and directed the period of investigation to the end of the first postnatal week and later. After the onset of myelination was determined, it was examined whether ‘silenced’ layer VI fibres in the brain develop myelin

according to the same pattern seen in control brains. Additionally, 'silenced' layer V and layer VI projections have been investigated at various adult ages, and an unexpected degeneration in silenced projections was observed. Transmission electron microscopic examination of corticospinal projections from 'silenced' layer V projections in spinal cord revealed that myelin does not form a compact layer but increasingly loose structure with multiple vacuoles. In the next step, myelination will be assessed when neuronal activity is altered by supressing the conduction of action potentials by introducing an additional potassium channel at the nodes of Ranvier via *in utero* electroporation. In summary, preventing neurotransmitter release in this mice did not affect the onset of myelination or fibre targeting but myelin membrane compaction as well as fibre and myelin maintenance.

Title: Proteolipid protein null mice exhibit altered numbers of oligodendrocytes

Authors: *E. A. GOULD[1], D. SHEPHERD[2], D. RESTREPO[1], W. MACKLIN[1];
[1]Univ. of Colorado Denver Sch. of Med., Aurora, CO; [2]Univ. of Colorado Denver, Aurora, CO

Abstract: Myelin is required for proper nerve conduction and normal axonal function. However, little is known about the impact of myelin that is present but dysfunctional. Proteolipid protein (PLP) is major constituent of myelin and is abundantly expressed by oligodendrocytes (OL). PLP knockout mice (PLP-null) generate myelin but exhibit progressive myelin dysfunction and eventual axonal degeneration. We determined that 6 month PLP-null mice had a dramatic increase in OL density by quantifying OL in cleared brain tissue with light sheet imaging. OL were labeled using a transgenic line that drives eGFP expression under the PLP promoter. By underclearing the samples, we were able to retain eGFP expression in the OL cytoplasm and quantify OL number. Histological examination of OL lineage markers in brain sections confirmed our results. Starting at 2 months of age, PLP-null mice showed a region-specific increase in OL density, specifically in the corpus callosum, striatum, olfactory bulb. However,

motor cortex and hippocampus OL density was unaltered. At 4 months and 6 months, OL density continued to increase in PLP-null mice overall, indicating a pathological recruitment of OL. Consistent with this hypothesis, labeling of proliferative events with EdU showed an increase in the number of newly generated OL in the olfactory bulb and motor cortex 3 weeks after EdU injection. In the olfactory bulb, the number of EdU labeled cells that were not OL lineage cells also increased. To determine the source of the EdU labeled cells we labeled with a 4 hour pulse of EdU and observed local proliferative events. Intriguingly, the number of cells proliferating locally in the olfactory bulb and motor cortex was unaltered, while the number of proliferating cells in the subventricular zone was increased in PLP-null mice. This data indicates that PLP-null mice exhibit a pathological increase in oligodendrogenesis emanating from the subventricular zone, leading to an increase in OL density in specific brain regions. Ongoing investigation aims at characterizing the pathophysiological process that results in altered OL numbers in PLP-null mice.

Title: Oligodendrocytes labelling with Sulforhodamine 101 depends on astrocytic uptake via the thyroid hormone transporter OATP1c1 (slco1c1)

Authors: *S. HÜLSMANN[1,2], L. HAGOS[2];
[1]Georg August Univ. Goettingen, Goettingen, Germany; [2]Univ. Med. Ctr., Göttingen, Germany

Abstract: The specific visualization of glial cells with fluorescence markers is an important issue in modern neurophysiology. To label astrocytes, the dye sulforhodamine 101 (SR101) is widely used. Here we investigated whether SR101 can be used for in vitro staining of oligodendrocytes in the CA1 region of the hippocampus and whether the known astrocytic transporter OATP1C1 (slco1c1) is required also for oligodendrocyte labeling. We used transgenic mice that expressed the green fluorescent protein under the control of the oligodendrocyte specific proteolipid protein (PLP) promotor, and found that oligodendrocytes indeed are labeled by SR101 in hippocampal slice preparations. After application of the OATP1C1-substrate L-Thyroxin a significant reduction of the oligodendrocyte staining was

observed. Since slco1c1 is not expressed in oligodendrocytes, we conclude that oligodendrocyte-labeling with SR101 requires SR101-uptake by astrocytes, which then diffuses to oligodendrocytes via heterotypic gap junctions of the pan-glial network. In summary, unequivocal identification of a particular cell type is not possible by SR101 only, and thus, extra caution is recommended when using SR101 in the future.

Title: A dual incretin receptor agonist is especially potent in reducing insulin resistance in brains of mild cognitive impairment (MCI) and Alzheimer's disease dementia (ADd) cases

Authors: *K. TALBOT[1], J. KVASIC[2], A. STUCKY[2], S. M. SHAH[2], K.-C. LEE[2], K. P. BAKSHI[2], M. CHATTOPADHYAY[2], A. KHAN[2], P. L. MCCLEAN[3], C. HOLSCHER[4], A. J. SAMOYEDNY[1], J. Q. TROJANOWSKI[5], R. WILSON[6], D. A. BENNETT[6], R. D. DIMARCHI[7], H.-Y. WANG[2];

Med. Ctr., Chicago, IL; [7]Indiana Univ., Bloomington, IN

Abstract: Introduction. While the FDA has approved several drugs for relief of AD symptoms, they do not meet criteria for clinical effectiveness nor for substantial slowing of disease progression. Many scientists are thus calling for testing drugs targeting novel causal factors in AD, among the most promising of which is *brain insulin resistance*, which can cause or promote many AD pathologies and symptoms and which we showed to be a common and prominent feature of AD even in the absence of diabetes (Talbot et al., *J. Clin. Invest.* 122: 1316-1338,

2012). In brains from the APP/PS1 mouse model of AD, MCI cases, and AD dementia (ADd) cases, we have accordingly tested highly potent antidiabetics for their ability to reduce brain insulin resistance. We specifically tested incretin receptor agonists (IRAs), which are agonists of glucagon-like peptide 1 (GLP-1) and/or gastric inhibitory peptide (GIP) receptors. Methods. An ex vivo stimulation method (Talbot et al., 2012; Wang, H.-Y. J. Neurosci. 9: 9773-9784, 2012) was used to quantify responses of the hippocampal formation (HF) from APP/PS1 mice, non-amnestic MCI (naMCI), amnestic MCI (aMCI), and AD dementia (ADd) cases to 30 min incubation in 1 or 10 nM insulin compared to controls. The human tissue was obtained from cases within 10 h of death. We quantified insulin-induced activation of the insulin receptor, insulin receptor substrate-1, and Akt. IRA effects on HF insulin responses were tested in mice 2 mo after daily 25 nmoles/kg body wt. injections (ip) of the GLP-1R agonist liraglututide (Victoza) and in humans 30-60 min after exposure of the HF to liraglutide (100 nM), a GIP receptor agonist (100 nM), or the dual GLP1/GIP receptor agonist (RO6811135, 100 nM). Results. In the HF from APP/PS1 mice, ip liraglutude treatment virtually abolished the profound insulin resistance in that brain area by 7 mo. of age. In the HF from MCI cases, all 3 IRAs reduced insulin resistance markedly ($p < 0.001$), but the dual IRA was superior to other IRAs in aMCI. In the HF of mid-to-late stage ADd cases, liraglutide and a GIPR agonist reduced insulin resistance to a small but significant degree ($p < 0.05$). Only the dual IRA, however, markedly reduced HF insulin resistance in the ADd cases ($p < 0.001$). Conclusions. Incretin receptor agonists significantly decreased HF insulin resistance in APP/PS1 mice, MCI cases, and ADd cases. In acute tests on human brain tissue, the most potent of these agonists was a dual GLP1/GIPR agonist, which was the only IRA that substantially reduced brain insulin resistance in ADd. Given the apparent linkage between brain insulin resistance and AD pathology and cognitive deficits, this dual IRA may prove to be an effective AD therapeutic.

Title: Unexpected retinal structure and changes in people with Down's syndrome, a high risk population for Alzheimer's disease

Authors: ***M. J. WALPERT**[1], E. M. NORMANDO[3], S. H. ZAMAN[2], F. M. CORDEIRO[3], A. J. HOLLAND[2];
[1]Psychiatry, [2]CIDDRG, Univ. of Cambridge, Cambridge, United Kingdom; [3]ICORG, Univ. Col. London, London, United Kingdom

Abstract: Retinal biomarkers have the potential to provide insight into the natural progression of Alzheimer's Disease (AD). Early markers of AD-related change are necessary to aid the development and testing of treatments and therapies. It is understood that an increased knowledge of AD in Down's syndrome will benefit AD in the general population, due to the similarities in the manifestation of the disease. The aim of this project is to examine the potential of retinal degeneration as an early biomarker for AD in adults with DS. People with DS have a high prevalence of early onset AD. Spectral-domain optical coherence tomography (SD-OCT) was used to assess the structure of the DS retina and to detect retinal nerve fibre layer (RNFL) thickness. Fifty-four participants with DS and 68 healthy controls underwent high-resolution OCT examinations of RNFL. Cognitive ability and a diagnosis of dementia was assessed in participants with DS and control participants were screened for dementia. We anticipated that the RNFL would be significantly thinner in participants with DS than healthy controls based on dementia research which strongly indicates a decline in RNFL thickness with severity of the disease. RNFL is also known to naturally decrease in thickness in normal ageing. However, our results showed that RNFL is significantly thicker, rather than thinner, in people with DS (controls mean =97.34μ (SD =8.07μ), DS mean 118.46μ (SD =11.68), p =<0.001). Additionally we found that the DS RNFL measurements do not decline with age as seen in normal ageing and in the dementia population (DS r = -0.062, p =0.671). We suggest that the increased retinal thickness may be caused by deposition of amyloid-beta (Aβ) plaques in the retina, the toxicity of which may in turn increase the rate of apoptotic cells in the retina. Apoptotic cell bodies may build up in the retina due to impaired phagocytosis in DS causing increased thickening. A new study is now underway to measure rates of apoptosis using a novel technique, Detection of Apoptosing Retinal Cells (DARC), which has the capability of visualising programmed cell death in individual cells *in-vivo* for the first time.

Title: Combination dosing of the novel M1/M4-selective muscarinic agonist NSX-0527 and peripheral muscarinic antagonists for the treatment of Alzheimer's disease

Authors: S. A. HANSON[1], J. C. OCKULY[1], J. D. BECK[1], *M. L. HENDRICKSON[2,1]; [1]NeuroSolis, Inc., Madison, WI; [2]BrainXell, Inc., Madison, WI

Abstract: Although muscarinic agonists have long held promise for CNS disorders such as Alzheimer's disease (AD), development has been stymied by poor central potency and the potential for muscarinic side effects at high doses. For example, the M1/M4-preferring agonist xanomeline demonstrated efficacy in AD patients in a Phase II trial, but was abandoned due to poor tolerability. More recently, the novel M1/M4-selective orthosteric muscarinic agonist NSX-0527 (and close-in analogue NSX-0559) has been developed. NSX-0527 shows good bioavailability (~75%) and brain penetration (~60%) along with excellent metabolic stability. A combination therapy including FDA-approved peripheral muscarinic antagonists was evaluated in animal models as an approach to improve tolerability of high oral doses of NSX-0527. The peripheral antagonists evaluated, darifenacin, glycopyrrolate, methscopolamine, propantheline, and trospium, have extremely low brain penetration, resulting in an absence of side effects while not impeding the CNS activity of NSX-0527. Thus, such fixed-dose combinations may allow for increased agonist doses to aggressively drive central muscarinic M1 and M4 activation, and would represent a potential first-in-class therapeutic for AD.

Title: Open label trial of Magnesium l-Threonate for adults with mild to moderate Alzheimer's disease

Authors: *N. L. RASGON[1], T. WROOLIE[1], K. WATSON LIN[2], A. KRAMER[3], D. BALZAFIORE[1];
[2]Psychiatry and Behavioral Sci., [1]Stanford Univ. Sch. of Med., Palo Alto, CA; [3]Palo Alto Univ., Palo Alto, CA

Abstract: In the United States, there are an estimated 5.2 million cases of Alzhiemer's Disease (AD), with AD and other dementias effecting nearly 1 in 3 senior adults. Emerging research on Magnesium l-Threonate (MGT), provides evidence that supplementation may be of benefit to people with AD. Preliminary human trials and animal experiments have found associations between oral MGT supplementation and cognitive improvement, as well as neurobiological changes, including upregulation of NMDAR signaling pathways. We conducted an open-label trail of MGT supplementation of 17 adults aged 60 and older with mild to moderate AD (MMSE 14-26). The study consisted of 2 months of MGT supplementation followed by a 4 month follow up period. All subjects were given a complete neurocognitive battery at baseline, 2 months and 6 months. 18-F FDG PET scans were conducted at the study's baseline and after 2 months of treatment. Our results indicate a significant improvement in MMSE score from baseline to 2 months (mean change = 1.57 points SD=.67, p=.035), and between baseline and 6 months (mean change = 1.21 points SD=.60, p=.062). There was no significant change between 2 and 6 months (4 months after treatment discontinuation). The RBANS attention index, subtest for semantic fluency, and coding subtest each indicated a maintenance of cognitive function from baseline through 2 months and a significant decline after discontinuation. 18F FDG-PET scan showed a significant increase in regional cerebral metabolism in brain regions between baseline and two months follow up, including the medial temporal region, prefrontal cortex, parietotemporal cortex, and posterior cingulate cortex. In summary, while existing research MGT supplementation provides a preliminary evidence for its benefits to in the treatment of AD, relatively little research has been conducted overall, particularly in humans. Given the plausible mechanism of action and evidence of the effects of treatment on cognition and regional cerebral brain metabolism, additional human clinical trials are warranted.

Title: SUVN-502, a pure 5-ht6 receptor antagonist - proof-of-concept study design in moderate alzheimer's disease patients

Authors: ***R. V. NIROGI**, K. MUDIGONDA, K. PENTA, G. BHYRAPUNENI, V. BENADE, N. MUDDANA, V. PALACHARLA, D. AJJALA, V. GOYAL, S. PANDEY, R. ABRAHAM, R. KAMBHAMPATI, T. BANDYALA, V. BHATTA, A. SHINDE;
Suven Life Sci., Hyderabad, India

Abstract: SUVN-502 was evaluated in healthy human subjects following single and repeated administration. SUVN-502 was well tolerated following single or multiple oral administrations. There were no clinically relevant or serious adverse events. SUVN-502 is a pure 5-HT_6 receptor antagonist and demonstrated robust efficacy in preclinical animal models. The effect of SUVN-502 was studied in combination with memantine and donepezil in object recognition task using rats. SUVN-502 was also evaluated for the modulation of neurochemical (brain extracellular acetylcholine using microdialysis) and electrophysiological properties (theta and gamma modulation) in combination with donepezil and memantine. The exposures required for efficacy was projected based on the concentrations of SUVN-502 and its active metabolite M1 of SUVN-502 in animal models. Co-treatment of SUVN-502 with memantine and donepezil significantly potentiated the procognitive effects when compared to memantine and donepezil treatment group. These effects were seen even after repeated treatments for 14 days. SUVN-502 potentiated the effects of donepezil and memantine in hippocampal acetylcholine levels and brain oscillatory activity. There were no significant changes in the exposures of SUVN-502 or donepezil or memantine in the co-treatment group. The enhanced procognitive effects seen in the group co-treated with SUVN-502, memantine and donepezil can be attributed to the augmentation of the cholinergic neurotransmission in the brain. Thus, combination of SUVN-502 with memantine and donepezil may offer a new therapeutic strategy for the symptomatic treatment of Alzheimer's disease. SUVN-502 and M1 of SUVN-502 achieved the projected efficacy concentrations and attained steady state on day 7 upon multiple administrations in elderly human subjects. SUVN-502 has favorable pharmacokinetic profile suitable for once a

day oral administration. SUVN-502 is being evaluated in moderate AD patients currently treated with donepezil and memantine. A total of 537 subjects aged between 50 to 85 years are being enrolled for phase 2 study in USA.

Psychosomatic Med., Rostock, Germany; [8]Univ. of Cologne, Dept. of Psychiatry, Cologne, Germany

Abstract: It has been proposed that the earliest pathology associated with Alzheimer's disease is the occurrence of abnormal tau in the locus coeruleus (LC) (Braak et al., 2011). Furthermore, there is clear evidence that LC tau pathology increases with age (Braak et al., 2011, 2015). Accompanying this effect is an age-related increase in neuromelanin, a pigmented polymer that results from the oxidation of noradrenaline and accumulates in the LC (Zucca et al., 2006). Thus MR sequences optimized to detect neuromelanin can be used to reliably locate the LC (Sasaki et al., 2006; Keren et al., 2009; Clewett et al., 2016) and may serve as a marker to assess structural changes in aging and disease. The aim of the work presented was to assess the signal intensity of the LC in young and healthy older adults using neuromelanin-sensitive MRI. We hypothesised older adults would demonstrate an increase in LC intensity owing to an age-related increase in neuromelanin. 25 young (22-30 years old; M:F 13:12) and 57 healthy elderly adults (61-80 years old; M:F 19:38) were scanned at 3T using a T1-weighted FLASH sequence (0.75mm isotropic resolution whole brain acquisition). In order to gain superior contrast and delineation of the LC, a study-wise template (Avants et al., 2008) was created from all subjects with good LC visualization (n=67). The LC and two unilateral reference regions in the left and right pons were subsequently segmented on the template and applied to all subjects. The remaining subjects with poor LC visualization were co-registered to the study-wise template and LC and reference masks were warped to each individual space for data extraction. LC signal intensity was determined as $LC_{CNR} = (LC_{intensity} - Pons_{intensity})/Pons_{intensity}$. A significant age-related increase was observed in right ($t_{80} = -2.21$, $p = <0.05$) and bilateral LC signal intensity ($t_{80} = -2.21$, $p = <0.05$). No significant age-related differences in mean intensity were observed in the left or right pons reference regions. Assessment of maximum (max) intensity voxels across all subjects revealed a significant unilateral difference, whereby greater signal intensity was observed in the left LC ($t_{81} = 4.73$, $p = <0.0001$). Significant age-related differences in LC max signal intensity were observed in left ($t_{81} = -2.73$, $p = <0.01$) and right ($t_{81} = -3.99$, $p = <0.0005$) LC hemispheres. No sex differences in mean or max LC signal intensity were observed. Our findings suggest estimating neuromelanin signal intensity may be a promising surrogate marker to assess the structural integrity of the human LC *in vivo*. Further studies are underway to assess how age-related accumulation of neuromelanin in the LC may impact memory and cognition.

Title: A translational program of AAV2-BDNF gene delivery into the entorhinal cortex for Alzheimer's disease: Development of MRI guidance for accurate gene targeting and distribution in non-human primates

Authors: *A. H. NAGAHARA[1], B. R. WILSON[1], I. IVASYK[1], I. KOVACS[1], S. RAWALJI[1], J. R. BRINGAS[2], P. J. PIVIROTTO[2], W. SAN SEBASTIAN[2], L. SAMARANCH[2], K. S. BANKIEWICZ[2], M. H. TUSZYNSKI[1,3];

Abstract: Alzheimer's disease (AD) is a progressive neurodegenerative disease with early pathology occurring in the entorhinal cortex (EC). Our previous findings demonstrate that gene delivery using AAV2-Brain-Derived Neurotrophic Factor (BDNF) represents a potential neuroprotective therapy to prevent cortical neuronal loss in early AD (*Nat Med* 2009; *J Neurosci* 2013), and we are performing long-term safety studies in non-human primates prior to proposing human clinical trials. Accurate targeting of the entorhinal cortex is technically challenging due to its deep location on the ventral surface of the brain, together with atrophy of the EC in AD. To ensure accurate targeting and vector distribution in the EC, we used an MRI-guidance method with co-infusion of the MR contrast agent gadoteridol as a new method for gene delivery in AD. 8 rhesus macaques received AAV2-BDNF ($3x10^8$ vp/µl) combined with 1 mM gadoteridol (MRI tracer) using an MR-compatible cannula inserted through a ball-joint array port surgically implanted on the skull. MRI scans performed with a 3 Tesla scanner provided T1, T2, MP-RAGE imaging to plan and visualize vector delivery. Compared to non-MR guidance methods, real-time MR guidance with co-infusion of gadoteridol enabled substantial improvements in vector targeting and distribution in the EC. The spread of gadoteridol in the EC on MR scanning corresponded closely with the distribution of BDNF immunolableing post-mortem. The volume of the AAV2-BDNF infused significantly correlated with the number of BDNF labeled cells and the volume of BDNF immunoreactivity in the EC. Furthermore, BDNF labeling revealed widespread increase of BDNF in the hippocampus through anterograde transport. These results indicate that MRI-guidance provides a method for accurate AAV2-BDNF delivery to the EC and for extending the distribution of BDNF into the hippocampus. We conclude that MRI guidance is

likely to enhance the safety and accuracy of gene delivery for Alzheimer's disease and other disorders.

Title: Relative incidence of seizures and myoclonus in Alzheimer's disease, dementia with Lewy bodies, and frontotemporal dementia

Authors: *S. DARWISH, A. J. BEAGLE, K. G. RANASINGHE, E. KARAGEORGIOU, K. A. VOSSEL;
Memory and Aging Center, Dept. of Neurol., Univ. of California, San Francisco, San Francisco, CA

Abstract: Background: Patients with dementia have increased susceptibility to seizures and myoclonus. Pathomechanisms for network hyperexcitability involving distinct disease-related proteins and brain regions have been proposed. The relative incidence of seizures and myoclonus in the three most common neurodegenerative dementias, Alzheimer's disease (AD), dementia

with Lewy bodies (DLB), and frontotemporal dementia (FTD) spectrum, is unknown.
Objective: Establish incidence rates of first unprovoked seizures and myoclonus in patients with AD, DLB, and FTD at our center.
Methods: Records of patients meeting diagnostic criteria for AD (n= 1,319), DLB (n= 178), and FTD (n=348) from an eight year interval (2006-2013) were reviewed for evidence of new-onset seizures and myoclonus. Subjects with childhood seizures, provoked seizures (e.g., cortical lesion) or provoked myoclonus were excluded. Cumulative probabilities of developing seizures and myoclonus were calculated and compared between diagnostic groups, and age-stratified incidence rate ratios (IRR) were calculated using rates of age-matched control populations from epidemiological studies.
Results: The cumulative probability of developing seizures after disease onset was 13.4% in AD, 14.7% in DLB, and 3.0% in FTD ($p = 0.006$, age-stratified log-rank). The IRR was 9.7 for AD, 9.7 for DLB, and 6.3 for FTD. The cumulative probability of developing myoclonus was 44.2% in AD, 58.1% in DLB, and 24.7% in FTD ($p < 0.001$). Seizures increased with earlier age-at-onset in AD (age 30-49 IRR 86.6; 50-69 IRR 20.7; 70+ IRR 1.9; $p < 0.0001$) and myoclonus increased with earlier age-at-onset for patients in all three groups (AD $p < 0.001$; DLB $p = 0.02$; FTD $p = 0.003$). Seizures and myoclonus were significantly associated; 33.3% of patients with seizures had myoclonus, whereas 10.2% of patients without seizures had myoclonus ($p < 0.001$). Seizures began an average of 3.9 ± 4.0 years after the onset of cognitive decline, and myoclonus began 5.4 ± 3.1 years after onset.
Conclusions: Seizures and myoclonus occur with greater incidence in patients with AD, DLB, and FTD than in the general population, but the rate varies with diagnosis and age-at-onset, suggesting varied pathomechanisms for neural network hyperexcitability. Both symptoms tend to occur early in disease progression, indicating they could herald the onset of neurodegenerative disease. As myoclonus and seizures are treatable features of dementia, patient quality of life could be improved with their early recognition and treatment.

Title: Localization of Peroxisome Proliferator Activated Receptor alpha in frontal cortex of Alzheimer's disease patients

Authors: *A. FRACASSI[1,2], S. MORENO[2], G. TAGLIALATELA[1];
[1]Mitchell Ctr. for Neurodegenerative Diseases, Dept. of Neurol., Univ. of Texas Med. Br., Galveston, TX; [2]Dept. of Sci., Univ. Roma Tre, Rome, Italy

Abstract: Alzheimer's disease (AD) is the most common form of dementia, particularly affecting the hippocampus and frontal cortex. The ensuing cognitive and memory impairments are associated with amyloid β-peptide (Aβ) accumulation, oxidative stress, altered lipid metabolism and inflammation. These mechanisms are reported to be regulated by a subfamily of nuclear receptors, referred to as Peroxisome Proliferator-Activated Receptors (PPARs), which include three isoforms α, β/δ and ɣ. Among these, PPARα has been suggested to play a neuroprotective role in acute and chronic brain pathologies. Indeed, *in vivo* and *in vitro* studies have demonstrated the beneficial effects of PPARα agonists in memory consolidation in AD models. In order to begin translating these observations in the actual AD brain, here we used immunofluorescence microscopy to study PPARα localization in the frontal cortex of AD patients (n=4) compared to control subjects (n=4). Our results showed a significant increase of PPARα in AD as compared to control. The enhanced expression of PPARα might represent a response to counteract the redox imbalance and consequent oxidative stress occurring during AD pathology. Indeed the expression of several antioxidant enzymes regulated by PPARα namely superoxide dismutases 1 and 2, catalase and glutathione peroxidase appears modulated. Interestingly both nuclear and cytosolic localization of PPARα was observed. Cytosolic localization is likely associated with non-genomic actions of PPARα known to reduce inflammatory responses. Double staining demonstrated a prevalent colocalization of PPARα with the astroglial marker GFAP as compared to the neuron-specific marker NeuN. This is observed in both control and AD brains, however with a significant increase in AD patients. Notably, PPARs activation has been reported to suppress the expression of proinflammatory genes, and considering the key role of astroglia in neuroinflammation our results suggest a compensatory action of PPARα in controlling inflammatory pathway in response to Aβ accumulation. On the basis of this preliminary study it appears that effective therapeutic intervention against neurodegeneration/neuroinflammation targeting PPARα and peroxisomes should be considered.

Title: Predicting co-variation of alzheimer's disease pathology from brain connectivity

Authors: *L. DIGMA[1], K. ARNEMANN[1], A. RAJ[2], W. JAGUST[1];
[1]Helen Wills Neurosci. Inst., Berkeley, CA; [2]Dept. of Radiology, Weill Med. Col. of Cornell Univ., Ithaca, NY

Abstract: The accumulation of amyloid-β is one of the pathological features associated with Alzheimer's disease (AD). The mechanism by which amyloid-β spreads throughout the brain, however, is not well understood. One hypothesis is that the toxic agent may propagate to distributed areas across the brain via neural connections. In this study, we test this transneuronal spread hypothesis by comparing connectivity measures in young, healthy subjects to the distribution of amyloid-β across cognitively normal, older subjects that harbor a significant amount of pathology.

Resting-state fMRI data from healthy, young subjects (N=78, age=23.9±2.8) were used to measure functional connectivity using Pearson's correlations between 78 regions of interest from the Desikan-Killiany atlas. Diffusion weighted MRI data from an independent subset of healthy, young subjects (N=14, age=23.1±4.8) were used to estimate structural connectivity between these regions. PiB-PET imaging was used to measure amyloid-β deposition in a subset of cognitively normal, older subjects (N=29, age=76.9±4.8). We then calculated co-variation of amyloid-β using Pearson's correlations of PiB-DVRs between every pair of 78 regions. For each region, we performed linear regression to assess the relationship between its functional connectivity to other regions and amyloid-β co-variation between it and other regions. A bootstrapping procedure was then conducted to compare amyloid-β co-variation between structurally and non-structurally connected pairs of regions.

We found functional connectivity to be a strikingly good predictor of amyloid-β co-variation for 68 of 78 of regions (R^2=0.30±0.12, $p<0.05$, Bonferroni corrected), such that more strongly functionally connected regions exhibited higher amyloid-β co-variation. Moreover, we found amyloid-β co-variation to be significantly higher between structurally connected regions ($p<1e-4$).

In conclusion, the strong relationship between connectivity measures derived from young and amyloid-β co-variation across older subjects lends support to the notion that amyloid-β spreads through neural connections. Additional work, such as longitudinal assessment, is necessary to further investigate the spreading mechanisms of amyloid-β.

Title: A P2Y6 receptor pro-drug modulates cerebrospinal fluid amyloid β1-42 in PS1/APP mice and in patients with mild Alzheimer's disease

Authors: *J. DONG[1,2], R. DOYLE[1], R. SCHREIBER[3], N. ROULEAUX[1,4], K. FLICK[1], P. HAYDON[1,2];
[1]Neurosci., Tufts Univ. Sch. of Med., Boston, MA; [2]GliaCure, Inc., Boston, MA; [3]Suadeo Drug Discovery Consulting LLC, Charlestown, MA; [4]Psychology and Neuroscience, Sch. for Mental Hlth. and Neurosci., Maastricht Univ., Maastricht, Netherlands

Abstract: The purinergic P2Y6 receptor stimulates microglial phagocytosis and has been identified as a potential molecular target for the treatment of Alzheimer's disease (AD). We have developed pro-drugs that yield agonists for this receptor and have evaluated their potential as a disease modifying treatment for AD. Aβ1-42 accumulates in the parenchyma and decreases in the cerebrospinal fluid (CSF) of both AD mouse models and patients. Our lead candidate, GC021109, was evaluated in a PS1/APP mouse model of AD. Preclinical studies revealed that GC021109 reduced plaque burden in the hippocampus and cortex, and simultaneously elevated Aβ1-42 in the CSF as well as restored memory formation. Investigational New Drug-enabling studies as well as a phase 1a single ascending dose study demonstrated that GC021109 was safe and well tolerated and exhibited dose proportional pharmacokinetics. In a double blind, placebo-controlled, phase 1b study, patients with mild to moderate AD (n=36) were dosed once daily with 1, 10 or 30mg of GC021109 for 28 days. CSF biomarkers of patients were analyzed at baseline and after 28 days of treatment. Similar to our preclinical studies, we observed a significant increase in Aβ1-42 in CSF following treatment. Patients with mild AD exhibited robust responses to GC021109 ($P<0.005$), while those with moderate AD were less responsive. Together these results suggest that GC021109 has the potential for a disease modifying treatment for AD.

Title: The use of human-based methods to undertake new strategies for Alzheimer's disease research and define "pathways of disease"

Authors: *A. LAM[1,2], F. PISTOLLATO[3], E. L. OHAYON[1];
[1]Green Neurosci. Lab., Neurolinx Res. Inst., San Diego, CA; [2]Res. Policy, Physicians Committee for Responsible Med., Washington, DC; [3]Inst. for Hlth. and Consumer Protection (IHCP), European Commission – DG Joint Res. Ctr. (JRC), Ispra, Italy

Abstract: Previously we investigated the translational challenges in Alzheimer's disease (AD) due to reliance on reductive animal models and their failure to manifest the pathogenesis of AD and related dementias. Although there has been some recognition of this bias, the advancement and expansion of under-privileged human-based research directions will require some fundamental paradigm shifts and a global effort. Here we present key examples in human-based tissue studies, computational modeling, induced pluripotent stem research and multi-scale non-invasive readouts that can provide the foundational knowledge needed to define "pathways of disease" at the level of complexity necessary to bridge the clinical translation gap in AD. We will discuss pilot initiatives to develop resources to support human-based research, including proposals for novel human dementia tissue resources, an open online xeno-free induced pluripotent stem cell toolkit, and the adoption of a conceptual framework based on "Adverse Outcome Pathways" (AOP) as already envisioned in the field of toxicology and regulatory testing. We also describe how this multi-pronged approach will provide more predictive, adaptive, ethical and personalized precision care in response to the pathogenesis of AD and related dementias.

Title: β- and α-secretase processing of amyloid precursor protein in the human central nervous system

Authors: *J. A. DOBROWOLSKA ZAKARIA[1], R. J. BATEMAN[2], R. J. VASSAR[1];
[1]Cell & Mol. Biol., Northwestern Univ. Feinberg Sch. of Med., Chicago, IL; [2]Washington Univ. in St. Louis, St. Louis, MO

Abstract: The amyloid hypothesis proposes that increased production or decreased clearance of amyloid-beta (Aβ) leads to higher order amyloid structures, such as oligomers and plaques that initiate a cascade of events, culminating in neuronal death which manifests as Alzheimer's disease (AD). Aβ is generated from the sequential cleavage of Amyloid Precursor Protein (APP) by β- and γ-secretase. APP, a transmembrane protein, may be processed in one of at least two pathways and is initially cleaved by either α-secretase or β-secretase (BACE1). α-secretase cleavage of APP, occurring more frequently under physiological conditions, precludes the formation of Aβ and produces non-toxic soluble APP-α (sAPPα). Alternatively, APP is initially cleaved by BACE1 releasing soluble APP-β (sAPPβ), and is subsequently cleaved by γ-secretase producing Aβ. Some studies found BACE1 protein and sAPPβ are increased in cerebrospinal fluid (CSF) and post-mortem AD brain. Our previous data demonstrate an increase in CSF sAPPβ: sAPPα ratio in AD subjects versus cognitively normal age-matched controls, indicating a shift toward BACE1 processing of APP under pathophysiological conditions. Further, a high positive correlation exists between sAPPβ and Aβ concentrations in human CSF. Additionally, a stable isotope labeling kinetics (SILK) study suggests that about 50% of AD patients may overproduce Aβ. Together these findings suggest increased BACE1 activity may cause increased Aβ in at least a subpopulation of AD patients, but this hasn't been assessed directly.
Using our previously developed highly sensitive SILK/immunoprecipitation/liquid chromatography-mass spectrometry methods, we are quantifying sAPPβ and sAPPα kinetics in CSF from human AD subjects and cognitively normal age-matched controls, in order to determine β- and α-secretase activity in human CNS. We hypothesize that approximately half of AD patients overproduce Aβ due to increased BACE1 activity, while the other half have decreased Aβ clearance. By directly measuring production rates of sAPPβ and sAPPα *in vivo*, we will determine if, and by how much, BACE1 activity is increased in AD subjects; this would allow for characterization of AD subpopulations most likely to benefit from BACE1 inhibitor

(BSI) treatment. These results will not only elucidate human CNS APP physiology and AD pathophysiology, but outcomes of this study may also prove useful for measuring pharmacodynamic effects of candidate therapeutics, such as BSIs. BACE1 is currently a high priority target for AD, and results of altered BACE1 activity in AD are critical for understanding AD pathophysiology and the development of disease modifying therapeutics.

Title: *In vivo* spectral FRET assay for monitoring PS1/γ-secretase conformational changes

Authors: *M. MAESAKO, J. HORLACHER, O. BEREZOVSKA;
Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Using Förster resonance energy transfer (FRET)-based imaging techniques, we have previously shown that familial Alzheimer's disease (AD) mutations in Presenilin 1 (PS1) increase proximity of the PS1 N-terminus (NT) to the large cytoplasmic loop domain, causing so called "closed" pathogenic PS1 conformation. On the other hand, several nonsteroidal anti-inflammatory drugs and γ-secretase modulators, which are known to decrease the Aβ42/40 ratio, induce PS1 "open" conformation. This indicates that PS1 conformational changes are tightly linked to changes of the Aβ42/40 ratio, presenting pathogenic "closed" PS1 conformation as a potential target for AD prevention.
It is well known that Ca^{2+} overload is observed in AD mouse models, and we have recently reported that an increase in intracellular Ca^{2+} levels triggers PS1 pathogenic "closed" PS1 conformation in cultured neurons. However, whether Ca^{2+}-driven PS1 conformational changes similarly occur *in vivo* is unknown.
For monitoring PS1 conformational change, we have previously developed a conformation sensitive FRET probe: G-PS1-R, in which wild type PS1 with enhanced green fluorescent protein (GFP) fused to the NT and red fluorescent protein (RFP) inserted into the cytoplasmic loop.
Here we establish a new *in vivo* assay to monitor PS1 conformational change in living mouse brain. For this, we constructed a vector encoding G-PS1-R under human Synapsin1 promoter for targeted neuronal expression, and developed Adeno associate virus (AAV) to express G-PS1-R in mouse cortical neurons. To evoke higher Ca^{2+} levels in neurons, we topically applied KCl under cranial window. Using multi photon microscopy, we verified that G-PS1-R probe is sensitive to reliably reflect allosteric conformational change of PS1 *in vivo*.

Title: Activity-driven PS1 phosphorylation is responsible for pathogenic conformational change of the PS1/gamma-secretase

Authors: *J. HORLACHER, M. MAESAKO, O. BEREZOVSKA;
Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Alzheimer's disease (AD) is a progressive, neurodegenerative brain disorder and together with other forms of dementia, it is one of the major causes of disability in later life. Senile plaques containing β-amyloid (Aβ) are a major pathological hallmark of AD. One of the enzymes mainly involved in the production of Aβ is Presenilin-1 (PS1)/gamma-secretase. More than 180 familial AD (fAD) mutations have been identified in its gene. Mostly all of them result in a similar biochemical, histological, and clinical phenotype – an increase in the Aβ42/40 ratio and early age of onset. As a mechanism of elevation of the Aβ42/40 ratio, we have shown that fAD mutant PS1 isoforms reveal pathogenic "closed" conformation. Such PS1 pathogenic conformational change was also observed in aging and in sAD brains, as determined by using Förster resonance energy transfer (FRET)-based imaging techniques.
It has been suggested that elevation of neuronal Ca^{2+} levels can enhance the production of Aβ, and Aβ42 in particular. But the underlying mechanisms remain unclear. We have recently reported that an increase in intracellular Ca^{2+} levels leads to a conformational change in PS1. This "closed" PS1 conformation, reflected by an increased proximity between N- and C-termini, is followed by up-regulation in the Aβ42/40 ratio. Here we investigate the mechanistic link between Ca^{2+} overload and PS1 pathogenic conformational change. First, we found that Ca^{2+} influx increases the level of phosphorylated PS1. Using phosphorylation-inhibited PS1 constructs in which serine (S)/ threonine (T), previously reported as a phosphorylation site, is substituted for alanine, we found that phosphorylation at three different domains in PS1 is involved in Ca^{2+} -driven PS1 pathogenic conformational shift. Furthermore, we quantified the amount of phosphorylated PS1 in human brains, and found that PS1 phosphorylation is significantly enhanced in the AD brains as compared to non-demented control brains. Collectively, our data indicate that Ca^{2+}-induced PS1 phosphorylation at the three domains may present a molecular mechanism of pathological conformational change in PS1/gamma-secretase, leading to amyloidogenesis.

Title: Phosphatase activity during sleep/wake cycles regulates APP processing and brain ISF amyloid-beta levels

Authors: C. E. WALLACE, H. M. EDWARDS, *J. R. CIRRITO;
Neurol., Washington Univ., Saint Louis, MO

Abstract: Alzheimer’s disease (AD) is initiated by the progressive accumulation of amyloid-beta (Abeta) peptide in the brain as toxic structures, such as Abeta oligomers and plaques. Evidence in both APP transgenic animal models and in humans suggests that brain Abeta levels fluctuate with the diurnal cycle; Abeta within the brain extracellular fluids are high during wakefulness and low during sleep. The diurnal fluctuation has been detected in the brain interstitial fluid (ISF) of APP transgenic mice and in the cerebrospinal fluid (CSF) of humans. In mice, increasing sleep pharmacologically suppresses brain ISF Abeta levels and, conversely, acute sleep deprivation increases ISF Abeta levels. Chronic alterations in sleep have a similar impact on amyloid plaque accumulation in these mice. We hypothesized that sleep is altering an intracellular signaling pathway that ultimately regulates Abeta generation and secretion into the brain ISF. We used in vivo microdialysis to measure brain ISF Abeta levels every hour over several days in living mice. Similar to previous studies, we detected a diurnal fluctuation in ISF Abeta levels during the sleep/wake cycle. Inhibiting Extracellular Regulated Kinase (ERK), increased ISF Abeta levels by 50% and blocked the fluctuation in ISF Abeta, suggesting that ERK plays a role in the diurnal rhythm of Abeta. Interestingly, ERK has been shown to be downstream of several neurotransmitter receptors (e.g. serotonin and NMDA receptors) which also regulate Abeta levels. SHP-2 is a phosphatase that dephosphorylates phospho-ERK to deactivate it. Inhibition of SHP-2 reduces ISF Abeta levels and also blocks the diurnal fluctuation. Our data suggest that there is an inverse relationship between the amount of phospho-ERK and the activity of SHP-2 which determines how much Abeta is produced in response to the physiological fluctuation in sleep/wake.

Title: Retromer and Rab2-dependent trafficking are involved in PS1 degradation by proteasomes in endocytic disturbance

Authors: ***N. KIMURA**[1], N. UEDA[1], T. TOMITA[2], K. YANAGISAWA[1];
[1]Dept. of Alzheimer's Dis. Res., Natl. Ctr. For Geriatrics and Gerontology, Aichi, Japan; [2]The Univ. of Tokyo, Tokyo, Japan

Abstract: Accumulating evidence shows that endocytic disturbance affects β-amyloid peptide (Aβ) cleavage from β-amyloid precursor protein (APP), suggesting that endocytic pathway deficits are involved in Alzheimer's disease pathogenesis. Presenilin-1 (PS1) is the catalytic core of the γ-secretase complex required for Aβ generation, and mutations of PS1 are the predominant cause of familial AD (FAD). Interestingly, several recent studies showed that PS1 mutations cause lysosomal abnormalities, suggesting that they may also cause endocytic disturbances. Most AD patients, however, do not have PS1 mutations. Thus, it remains unclear whether endocytic disturbances alone can affect PS1 localization and function. Previously, we showed that aging induces endocytic disturbance, resulting in the accumulation of Aβ and APP in enlarged endosomes. It remains unclear, however, whether PS1 localization and function are affected with endocytic disturbance. Thus we investigated the relationship between endocytic disturbance and PS1. In Neuro2a cells, we found that PS1 is transported from endosomes to the ER/Golgi compartments via retromer trafficking during endocytic disturbance. We also confirmed that PS1 interacts with vacuolar protein sorting-associated protein (VPS) 35 both *in vitro* and *in vivo*. Moreover, we found that PS1 is degraded by proteasomes via a Rab2-dependent trafficking pathway, only when endocytic disturbance occurs. These findings suggest that PS1 levels and localization within endosomes may be regulated by retromer trafficking and ER-associated degradation (ERAD), even if endocytic disturbance significantly induces the endosomal accumulation of APP and BACE1. Results of this study also suggest that retromer deficiency can affect PS1 localization in endosomes, where Aβ cleavage mainly occurs, possibly leading to enhanced Aβ pathology.

Title: Pen-2 plays a critical role in substrate binding

Authors: ***C. HU**[1], T. LI[2], J. XU[3], M. CUI[1], X. XU[1];
[1]Comparative and Exptl. Med., The Univ. of Tennessee, Knoxville, TN; [2]Tianjin Med. Univ., Tianjin, China; [3]Jilin Med. Univ., Jilin, China

Abstract: Presenilin enhancer-2 (Pen-2), presenilin-1 (PS1) or presenilin-2 (PS2), nicastrin (NCT), and anterior pharynx-defective 1 (Aph-1) have been considered the minimal essential components required to form an active γ-secretase complex. Specifically, PS is essential for substrates processing as the catalytic subunit of the complex. NCT has been reported to function as a substrate receptor. Aph-1 was believed to be essential to both assembly and maturation of the γ-secretase complex. Pen-2 was recognized as an important component for PS endoproteolysis to generate the N-terminal and C-terminal fragments of presenilin (PSN and PSC), which is a critical step in γ-secretase complex maturation. However, recent studies have shown that Pen-2 might be dispensable for PS endoproteolysis. Moreover, our recent study revealed that overexpression of both PS1N and PS1C failed to restore γ-secretase activity in Pen-2-knockout cells, indicating that Pen-2 might not be required only for PS endoproteolysis. Furthermore, our data demonstrated that deletion of Pen-2 had no effect on stabilization and dimer formation between PS1N and PS1C. These findings suggest that, in addition to PS

endoproteolysis of presenilin, Pen-2 may play a direct role in γ-secretase activity. To this end, our co-immunoprecipitation experiments strongly suggest that Pen-2 is essential for γ-secretase to interact with its substrates.

Title: Mechanism that BACE1 alternates the cleaving sites of human APP

Authors: ***T. SUZUKI**, A. KIMURA, S. HATA;
Hokkaido Univ., Sapporo-Shi, Japan

Abstract: APP is primarily cleaved at β-site (Asp1 of Aβ) by BACE1 to generate CTFβ/C99 from which Amyloid-β (Aβ) is produced. However, BACE1 alternatively cleave APP at β'-site (Glu11 of Aβ) to generate CTFβ'/C89, which is the amyloid lytic cleavage. It is important to understand a mechanism how BACE1 selects β- or β'-cleaving sites, because Aβ generation is the primary cause of Alzheimer's disease. We analyzed how BACE1 determines the cleavage site of APP. **Methods:** We first expressed mouse APP, and human APP with or without amino acid substitutions in N2a cells, and analyzed the generation of Aβ species (Aβ1-X and Aβ11-X) secreted into medium with immunoprecipitation-TOF/MS. We further analyzed localization of APP-CTFα and -CTFβ, C-terminal fragments of APP truncated by α-secretase (ADAM10/17) and BACE1 in mouse brain. We prepared the detergent (1% TritonX-100)-resistant membrane (DRM) and non-DRM fractions of mice brain and analyzed the membrane micro-localization of CTFα, CTFβ and CTFβ' by Western blotting. **Results:** N2a cells expressing mouse APP secreted lower levels of Aβ1-40 along with higher levels of Aβ11-40. By contrast, cells expressing human APP secreted higher levels of Aβ1-40 and lower levels of Aβ11-40. These results indicate that a major cleavage site of mouse APP is Glu11 site and that of human APP is Asp1 site. Two amino acids located on Aβ sequence are important to select Asp1 cleavage site. DRM fractionation study with mice brain shows that APP-CTFβ localized differently from APP-CTFβ' in

membrane fraction, suggesting that APP is cleaved by BASE1 in various membrane micro-regions. **Conclusions:** Major cleavage site of human APP by BACE1 is different from it of mouse APP, and f this alternative cleavage is caused by a difference of amino acid at two positions of Aβ sequence, contributing for selection of either β-site or β'-site. Studies with DRM fraction suggest that the alternative cleavage of human APP by BACE1 is also due to a cellular and membrane microenvironment in which APP and BACE1 localize.

Title: BACE1/BACE2 selectivity, the next frontier in beta-secretase inhibition for Alzheimer's disease: A mouse model of depilation-induced pigmentation for *In vivo* screening

Authors: *P. H. WEN[1], J. BRADLEY[1], M. JOHNSON[2], M. SOTO[3], M. BOURBEAU[4], D. HICKMAN[3], S. WOOD[1];
[1]Neurosci., [2]Discovery Technologies, [3]PKDM, [4]Medicinal Chem., Amgen Inc, Thousand Oaks, CA

Abstract: BACE1 is the most promising drug target for Alzheimer's disease as it mediates the initial cleavage of the amyloid precursor protein in the generation of pathogenic Abeta peptides. Numerous BACE1 inhibitors possessing satisfactory drug-like properties have been discovered, yet it has proven challenging to design potent molecules that are selective against other aspartyl proteases including the closely related homolog, BACE2. Recent investigations into the physiological functions of BACE2 have aided in this task. PMEL17 (Pigment cell-specific Melanocyte protein), a transmembrane protein involved in melanogenesis, has been identified as a novel BACE2 substrate. Proteolytic cleavage of PMEL17 by BACE2 releases fragments into melanosomes, mediating formation of a matrix of amyloid fibers required for melanin deposition. This may explain the hypopigmentation phenotype observed in BACE2 KO mice, in which defective PMEL17 processing could lead to abnormal maturation of melanosomes. Moreover, recent studies showed that chronic treatment of wild type mice with a non-selective BACE1 inhibitor causes hypopigmentation of the fur and skin, implicating BACE2 as a tissue-specific protease and an important pigmentation gene. In addition, BACE2+/- and BACE2-/- mice treated with a potent dual BACE1/BACE2 inhibitor display dose-dependent appearance of irreversibly hypopigmented hair. To identify best-in-class BACE1 inhibitors that are selective

over BACE2 we have developed novel in vitro and vivo screening assays. A high-throughput cell-based assay was established to monitor BACE2-mediated turnover of known BACE2 substrates. Pharmacodynamic effects of BACE1 inhibitors have been assessed in a mouse model of depilation-induced hair follicle cycling. Multiple genes required for melanogenesis, including tyrosinase, TRP1 & 2 and MITF, as well as protein levels of PMEL17 cleavage products were profiled in the skin at stages of the hair cycle following depilation in mice treated with BACE1 inhibitors.

Title: Palmitate-enriched diet increases BACE1 expression and ensuing Amyloid-Beta genesis by evoking ER stress and subsequent CHOP activation

Authors: *G. A. MARWARHA, J. SCHOMMER, J. LILEK, O. GHRIBI;
Biomed. Sci., Univ. of North Dakota, Grand Forks, ND

Abstract: Alzheimer’s disease (AD) is the most common form of dementia in the elderly that is histo-pathologically characterized by extracellular accumulation of aggregated Amyloid-β (Aβ) peptide as *neuritic senile plaques* and the intracellular accumulation of aggregated hyperphosphorylated protein tau (τ) as *neurofibrillary tangles.* The aspartyl protease BACE1 is indispensable for the engenderment of Aβ and catalyzes the rate-limiting step in Aβ genesis from AβPP. The expression of BACE1 protein as well as its enzymatic activity is significantly augmented in the AD brain. The etiology of AD is multifactorial and egregiously comprehended, but epidemiological studies have implicated a diet rich in saturated free fatty acids (sFFA) as a significant risk factor for developing AD. Palmitic acid (palmitate) is the most abundant long-chain free saturated fatty acid in the brain and the diet and higher palmitate levels in the plasma, as observed in obesity and diabetes, are inversely correlate with cognitive function. Recent cogent evidence has implicated endoplasmic reticulum (ER) stress as one of the culpable factors in initiating and fostering the deleterious neurodegenerative changes in AD. A multitude of studies have cogently demonstrated that sFFA such as palmitic acid evoke ER stress. Sustained

ER stress culminates in the increased expression of the transcription factor C/EBP Homologous Protein (CHOP, also called GADD153 or DDIT3). In addition to transcriptionally up-regulating the expression of a plethora of genes involved in ER stress response, increased expression of CHOP also enhances NF-κB signaling and transcriptional activity. NF-κB signaling and transcriptional activity positively and directly regulate the transcription of BACE1 and our earlier studies have demonstrated and unveiled a novel CHOP - NF-κB signaling pathway in the regulation of BACE1 expression. However, the extent to which palmitic modulates these pathways to impinge on BACE1 expression and subsequent Aβ genesis is not known. In this study, we determined the impact of high palmitate-diet on BACE1 expression and Aβ genesis and delineated the molecular mechanisms involved.

Title: Loss of BACE1 - but not BACE2 - function in mice results in decreased body weight, protection against diet-induced obesity and reduced anxiety.

Authors: ***T. W. ROSAHL**[1], L. A. HYDE[1], M.-F. CHAMPY[4], H. MEZIANE[4], C. CANASTO-CHIBUQUE1[1], K. JUHL[1], Z. LI[1], B. PETIT-DEMOULIERE[4], T. SORG[4], J. SCOTT[2], G. J. EIERMANN[1], J. N. CUMMING[2], E. M. PARKER[1], M. E. KENNEDY[3];
[1]In Vivo pharmacology, [2]Chem., Merck Res. Labs., Kenilworth, NJ; [3]Neurosci., Merck Res. Labs., Boston, MA; [4]Inst. Clinique de la Soris (ICS), Illkirch, France

Abstract: BACE1 (β-site amyloid precursor protein-cleaving enzyme 1) is a key enzyme in the production of toxic amyloid peptides and is highly expressed in the brain, but also to a lesser extent in major peripheral organs such as muscle and liver. In contrast, BACE2 is mainly expressed in peripheral tissues and enriched in pancreatic β cells where it regulates its cell function and mass. Previous reports demonstrated that loss of BACE1 function decreases body weight, protects against diet-induced obesity and enhances insulin sensitivity in mice (Meakin et al, Biochem. J. 441, 2875-296, 2012), whereas mice lacking Bace2 exhibit reduced blood glucose levels, improved intraperitoneal glucose tolerance and increased β cell mass (Esterhazy et al, Cell Metabol. 14, 365-377, 2011). Impaired glucose homeostasis and insulin resistance are

hallmarks of Type 2 diabetes, which is an important risk factor for AD (Alzheimer's disease). Therefore, we tested the contribution of the individual BACE isoforms to those metabolic phenotypes by placing Bace1 knockout (KO), Bace2 KO, Bace1/2 double knockout (dKO) and wild type (WT) mice on a high fat diet for 16 weeks. Bace 1 KO and Bace1/2 dKO mice showed decreased body weight, improved glucose tolerance and enhanced insulin resistance vs WT mice. Surprisingly, Bace2 KO mice did not show any significant differences in body weight, glucose tolerance or insulin resistance under our experimental conditions, indicating that lack of Bace1 - but not Bace2 - function contributes mainly to the metabolic phenotypic changes observed in Bace1/2 dKO mice. Although Bace1 KO, Bace2 KO and Bace1/2 dKO mice were normal in most behavioral assays, both the Bace1 KO and Bace1/2 dKO - but not the Bace2 KO - mice showed reduced anxiety. Only the Bace1/2 dKO mice were hyperactive in the open field and other locomotor activity assays during the light phase. Finally, chronic treatment of C57BL6 mice with 10 mg/kg/day of the dual BACE1/2 inhibitors MBi-3 or MBi-9 mixed in a HFD for 3 weeks resulted in a modest improvement of glucose tolerance. Our data suggest that inhibition of BACE1 has the greater role (vs BACE2) on any potential metabolic homeostasis improvements or anxiety behavior.

Title: Role of PSEN1 in neuronal differentiation and Alzheimer's disease - modeling human neurodegeneration in a dish

Authors: *C. PIRES[1], A. POON[1], B. SCHMID[2], T. T. NIELSEN[3], L. E. HJERMIND[3], J. NIELSEN[3], C. CLAUSEN[2], P. HYTTEL[1], B. HOLST[2], K. FREUDE[1];
[1]Univ. of Copenhagen, Frederiksberg C, Denmark; [2]Bioneer A/S, Hoersholm, Denmark; [3]Danish Dementia Res. Center, Rigshospitalet, Copenhagen Univ. Hosp., Copenhagen, Denmark

Abstract: Alzheimer's disease (AD) is the most common type of dementia and targets the cerebral cortex and certain subcortical regions. The familial (FAD) form shows early-onset symptoms and it is attributed to mutations in presenilin (PSEN) 1 and 2 and amyloid precursor protein (APP) genes. PSENs are constituents of the gamma-secretase complex and it correlates with increased toxic Aβ42 and senile plaques in AD brain. Sporadic (SAD) type has a late-onset and no causative genetic background has been identified except for apolipoprotein E (APOE) risk factor.
Human induced Pluripotent Stem Cells (hiPSC) allow for the generation of patient-specific neurons, providing *in vitro* tools for studying neurodegeneration. We have generated patient-derived PSEN1-hiPSCs carrying one of five different PSEN1 mutations (A79V, L150P, M146I, H214R and L282F). These PSEN1-hiPSCs were carefully characterized in regards to pluripotency by quantitative PCR and immunocytochemistry for key pluripotency genes/proteins. Furthermore, their differentiation potential was explored by embryoid-body formation and differentiation into all three germlayers. To assess even subtle disease phenotypes we have generated isogenic controls for each line via genome editing, by using the CRISPR-Cas9 system combined with ssODNs carrying the corrected nucleotide and inserted silent mutations. We are currently assessing disease phenotypes caused by different PSEN1 mutations including apoptosis (Caspase 3/7), cell ROS and autophagy assays, ELISAs to determine the relative increase in Aβ42 over Aβ40, spontaneous action potential and mitochondrial dysfunction, which is related to the "Ca^{2+} hypothesis" in AD. Moreover, terminally differentiated neurons from PSEN1, isogenic and sex/age-matched control lines are being analyzed via RNAseq to evaluate possible biomarker candidates, which will then be assessed/validated in the respective patients' CSF and blood samples, and also to evaluate if different mutation sites lead to distinct pathway alterations. Proteomics and metabolomics will also be studied so that a broad and detailed idea of the mutations' impact is constructed.

Title: Hif1alpha activates gamma-secretase and increases production of amyloid-beta in cells

Authors: *C. CARROLL, Y. LI;
Mem. Sloan-Kettering Cancer Ctr., New York, NY

Abstract: Alzheimer's disease (AD) is the sixth leading cause of death in the US, and there is currently no effective treatment or cure. One major risk factor for developing this disease is hypoxia, or low oxygen conditions, often times developed after the occurrence of a stroke. The brain is especially vulnerable to these changes in oxygen level, as it has the highest oxygen demand in the body. Understanding the relationship between hypoxia and AD could help guide future therapeutics. Amyloid precursor protein (APP) is first cleaved by either alpha or beta secretase, followed by cleavage by gamma-secretase. If APP is first processed by beta secretase, cleavage by gamma-secretase produces amyloid beta peptides of varying lengths. These peptides can then oligomerize and form the hallmark plaques found in AD brains.Previous reports have shown that hypoxia increases amyloid-beta production in both cells and mice. We aim to show that this increase in amyloid-beta is due to an increase in gamma-secretase activity. Hif1alpha, the master regulator of hypoxia, directly binds to gamma-secretase, increasing its activity and production of amyloid-beta, independent of its canonical, transcriptional role.

Title: A brain-derived Abeta42 surrogate marker in peripheral blood

Authors: *S. TAGAMI[1], K. YANAGIDA[1], T. TOMONAGA[2], T. IKEUCHI[3], M. WARAGAI[4], M. TAKEDA[5], M. IKEDA[1], M. OKOCHI[1];
[1]Osaka Univ. Grad. Sch. of Med., Suita Osaka, Japan; [2]Lab. of Proteome Research, Natl. Inst. of Biomed. Innovation, Osaka, Japan; [3]Dept. of Mol. Genetics, Brain Res. Institute, Niigata Univ., Niigata, Japan; [4]Higashi Matsudo Municipal Hosp., Tchiba, Japan; [5]Aino Univ., Osaka, Japan

Abstract: Objective: Amyloid beta42 in cerebrospinal fluid (CSF) is well established biomarker in Alzheimer's disease(AD). The value is utilized for diagnosis of preclinical AD and also for an indicator of therapeutic effect. However, Abeta42 in peripheral blood is not practically used as generally as that in CSF. Thus, as for a blood-based biomarker of AD, surrogate markers are necessary by which the level of brain Abeta42 generation can be estimated. We discovered APL1beta28, an Abeta42 surrogate marker, in human CSF and showed the APL1beta28 ratio (APL1beta28/total APL1beta) was elevated in CSF samples of FAD with PS1 pathogenic mutations, sporadic AD and MCI patients. Thus, the APL1beta28 ratio will be a biomarker which indicates Abeta42 generation in brain. To use this surrogate marker in large clinical studies, we have tried to detect and measure the level of this CNS peptide in peripheral blood.
Methods: We performed several biochemical treatments to purify plasma APL1beta28 and measure the levels by using LC/MS/MS system.
Results: We could successfully measure the level of the CNS APL1beta28 peptide in plasma. The concentration of APL1beta28 is 0.5pM, which is much less than that in CSF (500pM).
Conclusions: We have tried to develop Abeta42 surrogate marker in peripheral blood. The plasma APL1beta;28 ratio may be used to estimate the Abeta42 ratio in brain.

Title: Impaired synaptic transmission in the CA1 area of hippocampal slices of APPSwDutIowa/Nos2$^{-/-}$ (CVN) mice

Authors: M. V. KOPANITSA, J. PUOLIVÄLI, O. KONTKANEN, *R. HODGSON, A. NURMI, P. J. SWEENEY;
Charles River Discovery, Kuopio, Finland

Abstract: The CVN mouse model of Alzheimer's disease combines overexpression of the APP isoform 770 transgene that bears Swedish (K670N/M671L), Dutch (E693Q), and Iowa (D694N) mutations with a constitutive deletion of nitric oxide synthase 2. In addition to amyloid deposition, these mice exhibit aggregation of hyperphosphorylated tau and substantial neuronal loss. One of the brain areas that is profoundly affected by AD-like pathologies in CVN mice is the hippocampus. However, electrophysiological evidence of potential repercussions of excessive amyloid deposition and expression of hyperphosphorylated tau for synaptic transmission in the hippocampus has been lacking so far. To this end, we prepared hippocampal slices from 17-18-month-old CVN and aged matched control mice and, by using multi-electrode arrays (MEAs), recorded field excitatory postsynaptic potentials (fEPSPs) in the hippocampal CA1 area in response to stimulation of Schäffer collaterals. When recording input-output relationships, we noted that peak fEPSP amplitudes were smaller in slices from CVN mice, particularly at higher values of stimulus strength. The maximum fEPSPs comprised 3.3 ± 0.8 mV in slices from control animals, whereas in CVN mice responses were slightly but significantly lower (2.7 ± 0.7 mV; $P = 0.015$; 2-way nested ANOVA, main genotype effect). In addition, paired-pulse facilitation (PPF) at an interpulse interval of 50 ms was lower in slices from CVN mice (159.9 ± 2.2%) than in control mice (170.4 ± 4.3%, $P = 0.044$).Short theta-burst stimulation elicited stable long-term potentiation (LTP) of fEPSP amplitudes in slices from CVN and control animals. Sixty-five min after induction, LTP levels were similar in both genotypes (CVN: 151.0 ± 4.2%; control: 152.5 ± 3.3%; $P > 0.05$). We conclude that a moderate impairment of basal synaptic transmission parameters in hippocampal slices from CVN mice is probably a reflection of a neuronal loss in the hippocampus. Disturbances in PPF may be also partly linked to selective degradation of some populations of hippocampal interneurons previously observed in this model.

Title: GSK-3β-mediated phosphorylation of PICK1 regulates the GluA2-PICK1 interaction.

Authors: *S. YAGISHITA[1,2], M. MURAYAMA[2], T. EBIHARA[1], K. MARUYAMA[1], A. TAKASHIMA[2,3];
[1]Saitama Med. Univ., Saitama, Japan; [2]Lab. for Alzheimer's Disease, RIKEN Brain Sci. Inst., Saitama, Japan; [3]Dept. of Aging Neurobiology, Ctr. for Develop. of Advanced Med. for Dementia, Natl. Ctr. for Geriatrics and Gerontology, Aichi, Japan

Abstract: Alzheimer disease (AD) is the most common type of dementia, and the mechanisms leading to the onset of AD has been unknown. The hallmarks of AD are the deposition of amyloid β-protein (Aβ) and hyperphosphorylated tau, both of which have been shown to be related to long-term depression (LTD): Aβ dimers induce LTD, and the presence of tau is required for LTD induction. On the other hand, activation of GSK-3β, a critical molecular link between Aβ and tau, is required for LTD induction. Thus LTD has been recently regarded as an AD-related synaptic event.
LTD involves the removal of AMPA receptor subunit GluA2 from the synaptic plasma membrane. For the removal, GluA2 is required to interact with Protein interacting with C kinase 1 (PICK1). Here, we aimed to elucidate the relationships between GluA2, PICK1, GSK-3β, and tau.
We showed that GSK-3β phosphorylated PICK1 and that this phosphorylation promoted the GluA2-PICK1 interaction. We identified GSK-3β-mediated phosphorylation sites of PICK1. In particular, replacing the most C-terminal Ser416 with Ala disrupted the GluA2-PICK1 interaction, while substituting Ser416 with Glu or Asp retained this interaction, suggesting that phosphorylation at Ser416 residue was essential for the GluA2-PICK1 interaction. We also found that the presence of tau enhanced the GluA2-PICK1 interaction. However, the deletion of Ser416 did not affect the GluA2-PICK1 interaction, and the substitution of Ser416 with Ala did not alter the PICK1-PICK1 interaction. Using image analysis in COS-7 cells with GFP-fused PICK1, we showed that substitution of Ser416 with Ala increased the formation of GFP-positive

clusters, suggesting an increase in the association of PICK1 with the membrane. This may have resulted in the dissociation of the GluA2-PICK1 complexes.
This study proposes a new model for regulating the GluA2-PICK1 interaction and provides new insights into the molecular mechanisms leading to the onset of AD.

Abstract: Alzheimer’s disease (AD) is a devastating neurodegenerative disorder clinically characterized by gradual and progressive memory and cognitive decline. AD is currently conceptualized as a disease of synaptic failure, and novel clinical and animal model studies indicates that synaptic impairments are the most robust pathological feature that better correlates with dementia, implicating it as important to the disease process. However, the underlying molecular mechanisms that impair the synaptic function and cause synaptic loss in AD is poorly understood, especially at early stage of the disease. Hence, studies designed to elucidate the mechanisms by which the synaptic function is affected early in AD will provide greater insight into the onset of cognitive deficits in AD patients, and it will allow identifying novel treatment targets. Here, we study in a preclinical AD model, the 3xTg-AD, how the synapses are

compromised early in the disease. Our study reveals that 3xTg-AD display significant reduction in the spine densities and important structural change at 6-7 month of age. These alterations are associated with Long-Term Potentiation (LTP) deficits and alterations in synaptic receptor trafficking. These important synaptic alterations are associated with elevated level of Aβ and tau pathology in the synapses. Finally, the levels of actin-related proteins are diminished in 3xTg-AD mice, which are crucial to maintain the shape and function of the synapse. Overall, our study indicates that synaptic alterations occur early in the pathobiology of AD and elucidating these mechanisms might offer novel therapeutic targets for AD patients.

Title: Early changes in structure and function of gray matter axons in a mouse model of Alzheimer’s disease

Authors: D. PEKALA, *M. RAASTAD;
Dept Physiol, Emory Univ. Sch. of Med., Atlanta, GA

Abstract: Gray matter axons (GMAs) are the most common type of axon in the mammalian cortex. These axons are unmyelinated, are extremely thin (diameter on average 0.17 μm), and form *en passant* synapses at boutons distributed along their entire length. The function of GMAs involves action potential propagation and transmitter release. The specific morphology together with complex function indicates vulnerability of GMAs to pathological conditions. We have developed a method which allows to investigate structural changes of GMAs during the process of neurodegeneration in Alzheimer’s disease (AD). Together with changes in morphology we have also followed impact of AD on function of these axons. Experiments were performed on APP/PS1 transgenic mice that co-express five familial Alzheimer’s disease mutations (5xFAD) and WT controls. In order to detect structural changes, GMAs in hippocampus and cerebellum were labelled with lipophilic dye (DiI). Next, we measured intensity profiles of typical GMAs and estimated the ‘**bouton contrast**’ between each bouton and its adjacent thin axon and calculated the inter-bouton interval (**IBI**). To study functional changes, we investigated short-

term modulation of synaptic strength in two pathways of hippocampus: stratum radiatum (SR) and stratum lacunosum-moleculare (SLM). Extracellular recordings of field synaptic potentials (fEPSP) were performed on 300 μm transverse slices at 36 °C in the presence of APV (50 μM) in recording solution, to reduce the postsynaptic modulation of synaptic strength. Two months before symptoms or amyloid deposits have been reported in these mice bouton contrast was higher in 5xFAD compared to WT mice in axons from hippocampus and cerebellum. The IBI of hippocampal GMAs were longer in 5xFAD than WT controls. Boutons on hippocampal axons tended to be more regularly spaced in 5xFAD than in WT, while cerebellar axons were not different in the two groups. Recordings of fEPSP showed that synaptic facilitation was reduced in the 5xFAD in both SR and SLM compared to WT. These findings combined with the structural changes strongly support the hypothesis that GMAs change early during neurodegeneration.

Title: Genetic targeting of APP in hippocampus demonstrates that synapses postsynaptic to neurons expressing APP are the earliest sites of injury

Authors: *E. VICARIO ORRI, K. CHIANG, S.-H. TYAN, S. LEUTGEB, E. H. KOO; Neurosciences, Univ. of California San Diego, LA Jolla, CA

Abstract: The mechanisms by which Aβ causes synaptic dysfunction in Alzheimer's disease (AD) are not well understood. To date, it is not possible to determine whether Aβ-induced synaptic injury is initiated by the pre- or post-synaptic neurons and how injury is propagated. To address these questions, we targeted the amyloid precursor protein (APP) to CA1 or CA3 neurons by combining Cre/loxP and Tet-Off systems, thus providing temporal and spatial control of APP expression. Synapse loss was quantified by immunostaining of synaptic markers in dendritic layers of CA1 and CA3 neurons. In 12-month-old CA3-3xTg mice, where APP was expressed selectively in CA3 neurons, there was a significant 9% decrease in synaptophysin and

PSD-95 puncta only in the areas where axons from CA3 neurons synapse onto dendrites of CA1 neurons. This is consistent with our previous observation that LTP was impaired only in synapses where APP was expressed in pre- but not postsynaptic neurons. In 18-month-old animals, significant reductions in synaptophysin and PSD-95 (11-13%) were observed in dendritic fields of axons from CA1 as well as of CA3 neurons indicating a spread of injury also to synapses that were presynaptic to neurons expressing APP. Treatment with doxycycline for two weeks reversed both synaptic loss and LTP deficits in 12-month-old CA3-3xTg mice. Consistent with these observations, preliminary studies in 10-month-old CA1-3xTg mice did not reveal any synapse loss in CA1 dendritic fields but a trend towards a decrease in the subiculum. These results show that synapses most vulnerable to Aβ-induced injury are located postsynaptic to where APP was expressed. Interestingly, our data suggest that in this rodent model, synaptic injury with respect to reduction in LTP and synapse loss is not irreversible.

Title: Aβ-induced caspase activation and synaptic injury from APP C99 fragment is prevented in the APP D664A mutant that inhibits caspase-mediated cleavage

Authors: G. PARK[1], B. MIDTHUNE[1], M. NAVARRO[2], R. MALINOW[1], G. SALVESEN[2], *E. H. KOO[1];
[1]Dept Neurosciences, UCSD, La Jolla, CA; [2]Sanford Burnham Prebys Med. Discovery Inst., La jolla, CA

Abstract: Loss of synapses is a characteristic feature of Alzheimer’s disease (AD) and is believed to underlie the cognitive impairment in AD patients. The precise mechanisms of synaptic dysfunction and synapse loss are not well understood although it has been hypothesized that amyloid-β protein (Aβ) contributes to this process. We have previously proposed that an amyloid precursor protein (APP)-dependent pathway of Aβ toxicity related to cleavage of APP by caspases or caspase-like proteases at position 664 (APP695 numbering) contributes to synaptic injury and neuronal death. Here, we further examined the contribution of this pathway

to synaptic injury in organotypic neuronal slice cultures expressing APP D664A mutation designed to block cleavage of APP by caspases. Using a method previously reported to demonstrate Aβ-mediated synaptic depression in organotypic slice cultures, we confirmed a reduction in AMPA- and NMDA-mediated currents after expression of wt C99 fragment. However, this impairment was absent in neurons expressing C99 D664A, indicating that replacing the aspartate residue at position 664 to render APP non-cleavable is neuroprotective to Aβ-mediated neuronal toxicity. Interestingly, caspase 3 activity, as assayed by DEVD-afc cleavage, was elevated in slice cultures infected with wt C99, but was reduced in cultures infected with D664A mutant. This reduction was also seen in western blotting of activated caspase 3 and 6 as well as by the presence of caspase cleavage products (actin, synaptophysin and GADPH) in C99 wt but not D664A infected slice cultures. Lastly, incubation of purified caspases (3, 4, 6, 7, 8 and 9) with APP and C99 immunoprecipitated from HEK293 cells indicated that caspase 3 exhibited the highest activity in cleaving APP at position 664 in vitro. Our results demonstrated that neurons expressing C99 D664A were more resistant to synaptic injury than neurons expressing wt C99, consistent with the hypothesis that APP cleavage leads to the release of the putative C31 peptide from the APP C-terminus. Interestingly, the D664A mutant appears to block the activation of caspases detected after expression of C99, suggesting that the release of C31 peptide may be one mechanism by which Aβ is synaptotoxic. However, the latter cannot be ascertained from the current approach because the D664A substitution may have altered other pathways unrelated to C31 that contribute to neuronal injury.

Title: Fingolimod modulates NMDA receptor properties in rat hippocampal slices

Authors: *S. ATTIORI ESSIS, M.-E. LAURIER-LAURIN, É. PÉPIN, M. CYR, G. MASSICOTTE;
Biologie Médicale, Univ. Du Québec À Trois-Rivières, Trois-Rivieres, QC, Canada

Abstract: Sphingosine-1-phosphate (S1P) is a ceramide derivative serving not only as a regulator of immune properties but also as a modulator of synaptic plasticity in the brain. To better understand the mechanism underlying the effects of S1P on brain plasticity, we

investigated the potential impact of S1P receptor activation on NMDA receptor subunits. We used acute rat hippocampal slices as a model system, and determined the effects of the active phosphorylated S1P analog, fingolimod (or FTY720P). Treatment with FTY720P significantly increased phosphorylation of GluN2B-containing NMDA receptors at Tyr1472. This effect appears rather specific, as treatment with FTY720P did not modify other phosphorylation sites of GluN receptors. Pre-treatment of hippocampal slices with the compounds W146 and PP1 indicated that FTY720P-induced GluN2B phosphorylation at Tyr1472 epitopes was dependent on activation of S1P receptor subunit 1 (S1PR1) and Src/Fyn kinase, respectively. Cell surface biotinylation experiments indicated that FTY720P-induced GluN2B phosphorylation at Tyr1472 was also associated with increased levels of GluN1 and GluN2B subunits on membrane surface, whereas no change was observed for GluN2A subunits. These results suggest that activation of S1P receptors might enhance synaptic plasticity in the hippocampus by upregulating GluN2B phosphorylation in rat hippocampal slices, resulting in increased levels of receptors in neuronal membranes.

Title: Melanocortin 4 receptor activation ameliorates synaptic plasticity impairment in a mouse model of Alzheimer’s disease

Authors: *M. TIAN[1,2,3], Y. SHEN[1,2,3], F. GONG[1,2,3], A. K. Y. FU[1,2,3], N. Y. IP[1,2,3];

Abstract: Amyloid-beta (Aβ) accumulation leads to synaptic plasticity impairment and cognitive dysfunction in Alzheimer's disease (AD). We previously demonstrated that the G-protein-coupled receptor melanocortin 4 receptor (MC4R) is involved in the regulation of synaptic plasticity in the mouse hippocampus. Here, we show that the expression of the endogenous agonist of MC4R precursor polypeptide, pro-opiomelanocortin (POMC), changes along aging in the hippocampi of APP/PS1 mice, an AD mouse model. Interestingly, while the percentage of mature dendritic spines and spine size were reduced in the hippocampal cornu ammonis 1 (CA1) region in APP/PS1 mice, delivery of the MC4R agonist D-Tyr MTII reversed these defects. Furthermore, MC4R activation alleviated hippocampal synaptic plasticity impairment (i.e., long-term potentiation) in APP/PS1 mice. Interestingly, MC4R knockdown in the APP/PS1 mouse hippocampus abolished the rescue effect of D-Tyr MTII, suggesting that the specific activation of MC4R is critical for restoring synaptic functions in APP/PS1 mice. Our findings collectively demonstrate that activation of MC4R signaling in the hippocampus ameliorates the impaired synaptic plasticity in APP/PS1 mice, suggesting that MC4R signaling pathway might present potential targets for therapeutic interventions for AD.

Title: MC4R activation alleviates amyloid-beta-induced synaptic dysfuntion

Authors: *F. GONG[1,2,3], Y. SHEN[1,2,3], M. TIAN[1,2,3], A. K. Y. FU[1,2,3], N. Y. IP[1,2,3];

Abstract: Activation of melanocortin 4 receptor (MC4R), which is well known for its role in regulating energy homeostasis, enhances synaptic plasticity in mouse hippocampus via the cAMP/PKA-dependent pathway. In Alzheimer's disease, impaired hippocampal synaptic plasticity is suggested to be induced by soluble amyloid-beta. Here, we show that treatment of cultured hippocampal neurons with amyloid-beta reduced synaptic transmission, and the reduction could be reversed by MC4R activation. Furthermore, the rescue action of MC4R at synapses was mediated via the cAMP/PKA-dependent signaling pathway. Treatment of acute mouse hippocampus slices with MC4R agonist abolished the amyloid-beta-induced impairment in cAMP/PKA signaling and synaptic plasticity. Hence, our findings collectively indicate that MC4R activation alleviates the amyloid-beta-induced synaptic deficit in hippocampal neurons in a cAMP/PKA-dependent manner. Further mechanistic studies of the causative link between MC4R/cAMP/PKA signaling with synaptic dysfunctions observed in AD may provide insights into the potential development of MC4R as a molecular target of the disease.

Title: Understanding the melanocortin microcircuit in the mouse hippocampus

Authors: ***Y. SHEN**[1,2,3], M. TIAN[1,2,3], F. GONG[1,2,3], Y. ZHENG[1,2,3], A. K. FU[1,2,3], N. Y. IP[1,2,3]; [2]Mol. Neurosci. Ctr., [3]State Key Lab. of Mol. Neurosci., [1]The Hong Kong Univ. of Sci. and Technol., Hong Kong, China

Abstract: Hippocampal synaptic plasticity is the major cellular mechanism underlying learning and memory. Dysfunction or failure of hippocampal synaptic plasticity is associated with the development of various neurological disorders such as Alzheimer's disease. Hence, studying the functional regulation of synaptic plasticity not only enhances our understanding of learning and memory, but also elucidates the pathophysiology of dementia-related neurodegenerative diseases. Interestingly, melanocortins, the pro-opiomelanocortin (POMC)-derived peptides originally shown to regulate energy metabolism, are implicated in learning and memory enhancement. Here, we demonstrated that melanocortin 4 receptor (MC4R) plays an important role in the regulation of hippocampal synaptic plasticity. Long-term potentiation in the hippocampal CA1 region was significantly enhanced by *in vivo* MC4R activation and attenuated by MC4R knockdown. To further study the circuitry and mechanisms underlying melanocortins and MCRs involved in hippocampal synaptic plasticity, we mapped the circuitry of POMC/MCRs in the mouse hippocampus. We also confirmed melanocortin secretion in the hippocampus upon activity stimulation. These findings help to elucidate the hippocampal circuitry involved in learning and memory as well as the functions of the melanocortin system in the mammalian brain. Furthermore, the findings reveal a functional association between brain metabolism and cognition.

Title: Dysregulation of microRNA188 expression causes cognitive impairments in Alzheimer's disease by inducing synaptic deficit

Authors: *H. KIM[1], K. LEE[1], K. AN[2], O.-B. KWON[2], S. PARK[2], J. CHA[1], M.-H. KIM[1], Y. LEE[2], J.-H. KIM[2], K. CHO[3], H.-S. KIM[1];

Abstract: MicroRNAs have emerged as key factors in development, neurogenesis and synaptic functions in the central nervous system. In the present study, we investigated a pathophysiological significance of microRNA-188 (miR-188) in Alzheimer's disease (AD). We found that $A\beta_{1-42}$ treatment diminished miR-188-5p expression in primary hippocampal neurons and that miR-188 rescued $A\beta_{1-42}$-mediated synapse elimination and synaptic dysfunctions. Moreover, the impairments in cognitive function and synaptic transmission observed in 7-month-old 5Xfamilial AD (5XFAD) transgenic mice, were ameliorated via viral-mediated expression of miR-188. miR-188-5p expression was down-regulated in the brain tissues from AD patients and 5XFAD mice. The addition of miR-188 rescued the reduction in dendritic spine density in the primary hippocampal neurons-treated with oligomeric $A\beta_{1-42}$ and cultured from 5XFAD mice. The reduction in the frequency of mEPSCs was also restored by addition of miR-188. The impairments in basal fEPSPs and cognition observed in 7-month-old 5XFAD mice were ameliorated via the viral-mediated expression of miR-188 in the hippocampus. Furthermore, we found that miR-188 expression is CREB-dependent. Taken together, our results suggest that dysregulation of miR-188 expression contributes to the pathogenesis of AD by inducing synaptic dysfunction and cognitive deficits associated with Aβ-mediated pathophysiology in the disease

Abstract: Alzheimer's disease (AD) is a neurodegenerative disorder that has become a compelling global public health concern. Besides pathological hallmarks such as extracellular amyloid plaques, intracellular neurofibrillary tangles, and loss of neurons and synapses, clinical reports have also shown that epileptiform activity, even seizures, can occur early in the disease, particularly in familial AD. Moreover, such hypersynchronous network activity might also be an integral part of early pathological events in sporadic AD. Therefore, studying the mechanisms underlying AD related network dysfunction and its relation to cognitive decline is an important aspect in AD research. The APP-NL/F-KI novel mouse model of AD has been generated by a gene knock-in approach, and it most closely replicates the pathologies found in human AD when compared to other existing transgenic mouse models. In this new model, we have studied potential alterations in synaptic function in parietal cortex layer II/III pyramidal cells in acute brain slices. Our data from whole-cell recordings show that compared to age-matched control WT mice, in ~15-month-old APP-NL/F-KI homozygous mice: (1) the average amplitudes of both sEPSCs and sIPSCs were decreased in the pyramidal cells (sEPSC: 29.12 ± 1.50 pA vs. 22.70 ± 0.66 pA, $p<0.01$; sIPSC: 66.14 ± 6.12 pA vs. 39.64 ± 3.31 pA, $p<0.01$; n=10 vs. n=7; WT vs. homo); (2) particularly, the average amplitude of large sIPSC events (as identified through bimodal amplitude distributions) was smaller (133.90 ± 15.20 pA vs. 75.78 ± 11.07 pA; WT vs. homo; $p<0.05$); (3) the fraction of multi-event (≥ 2) bursts among the large sIPSC events was significantly lower (0.44 ± 0.03 vs. 0.31 ± 0.04; WT vs. homo; $p<0.05$). These alterations could indicate deficits in perisomatic-targeting PV-expressing interneurons (PV INs), which generate strong inhibition on their postsynaptic targets. Previous studies in the APP-overexpressing mouse model of AD have revealed diminished PV IN intrinsic excitability caused by reduced expression of voltage-gated sodium channel Nav1.1. Our present findings are consistent with this hypothesis, but further experiments will have to be done in the APP-NL/F-KI model to investigate the level of Nav1.1 expression in PV INs. Moreover, PV IN dysfunction could lead to abnormal gamma oscillations, which will disturb normal cortical network synchrony and lead to epileptiform activity and cognitive impairment in the transgenic animals. In summary, our findings on the altered synaptic activity in the novel mouse model of AD will help us understand the mechanisms underlying network hyperexcitability that is commonly found in this disorder.

Title: Synaptic zinc deficiency induces neuronal hyperexcitability and impairs adult neurogenesis in the hippocampus of ZnT3KO transgenic mice

Authors: *E. VOGLER[1], X. WANG[3], S. MICHALSKI[3], X. GAO[4], M. MAHAVONGTRAKUL[1], R. BOHANNAN[2], J. CHEN[4], J. A. BUSCIGLIO[1];

Abstract: Zinc is enriched in the mossy fiber tract of the hippocampus, where it is transported into synaptic vesicles at glutamatergic synapses by the ZnT3 protein and released during excitatory neurotransmission. Research has demonstrated that zinc modulates learning and memory, synaptic plasticity, synaptogenesis and synapse maturity. Zinc also reduces neuronal excitability, enhances inhibitory neurotransmission, suppresses excitatory neurotransmission, and delays development of seizures in models of epilepsy. Release of zinc during synaptic activity is associated with seizures through observations that ZnT3 knockout mice (ZnT3KO), which lack and therefore do not release synaptic zinc, are susceptible to induced seizure activity. ZnT3KO mice also have age-dependent cognitive impairment and alterations in neurotrophic and synaptic proteins. These observations suggest that the lack of synaptic zinc may also impair neurogenesis in an age-dependent manner. In fact, neurogenesis is regulated in part by synaptic activity and cell signaling pathways that are altered in aged ZnT3KO.
We investigated the effects of the genetic removal of synaptic zinc on neuronal activity and adult neurogenesis in the hippocampus through EEG and through immunohistochemistry for markers of seizure activity, neural stem cell proliferation and mature neuron production in ZnT3KO transgenic mice. We found excessive neuronal spiking activity starting at 2 month of age in ZnT3KO mice and age-dependent increases in markers of seizure activity beginning at 6 months of age in ZnT3KO hippocampus. We also found that at 8 months of age ZnT3KO have impaired neural stem cell proliferation and mature neuron production in the hippocampus.
These results indicate that lack of synaptic zinc induces neuronal hyperactivity in young animals

which results in impaired hippocampal neurogenesis, a component of neuronal plasticity that is critical for normal learning and memory, by 6 months of age, offering a mechanistic explanation for the age-dependent cognitive impairment in ZnT3KO mice at 6 months. Future experiments investigating the effects of the suppression of neuronal hyperactivity on neurogenesis and cognition in ZnT3KO mice may lead to targets for therapeutic interventions in pathologies where the modulatory role of zinc on neurotransmission is impaired.

Title: Abnormal increased basal EEG activity in the ZnT3KO mouse model of Alzheimer's Disease

Authors: ***M. MAHAVONGTRAKUL**, E. VOGLER, J. YAO, A. TRAN, R. F. STEVENSON, D. TRAN, J. BUSCIGLIO;
Univ. of California, Irvine, Irvine, CA

Abstract: Alzheimer's Disease (AD) patients have increased risk of nonconvulsive seizures; however, only recently has hyperexcitability become a major focus of AD research. Synaptic zinc, packaged into vesicles via the zinc T3 (ZnT3) transporter, is co-released with amyloid beta (Aβ) during neurotransmission and is implicated in both oligomer formation and modulation of excitatory neurotransmission. ZnT3KO mice exhibit age-dependent increases in markers of seizure activity, synaptic loss, neurodegeneration, and cognitive impairment, which can be reversed by chronic, but not acute, treatment with the antiepileptic drug Levetiracetam. Thus, the loss of zinc neuromodulation emerges as a key element in the development of hyperexcitability, leading to cognitive decline. We further investigated the role of zinc in this pathological process by examining EEG profiles in WT and ZnT3KO mice. Fifteen-month old ZnT3KO and WT mice underwent a novel method of EEG surgery, with subcranial electrodes placed over the medial

prefrontal cortex and parietal cortex. A Neurologger device was attached to each mouse to record EEG activity for 24-48 hours. The data were analyzed using custom MATLAB scripts which characterized the frequency and amplitude of the waveforms from the different recording electrodes, as well as the synchrony between each recording site. ZnT3KO mice exhibited basal hyperexcitability compared with their WT counterparts, as indicated by an increase in both frequency and amplitude of the EEG waveforms. These mice also exhibited hypersynchronous firing across all electrodes as indicated by a decrease in signal variance among all four recording electrodes and an increase in amplitude accompanying a decrease in frequency in the summated EEG trace. These results indicate that electrical discharge in ZnT3KO mice is abnormal. This is significant because chronic hyperexcitability may lead to maladaptive circuit plasticity, neurodegeneration, and cognitive impairment in both AD mouse models and AD patients. Ongoing studies are focusing on characterizing the imbalance of excitation and inhibition, as well as defining the onset of abnormal EEG activity in relation to the time point at which cognitive impairment becomes apparent in ZnT3KO mice.

Title: Modified synaptic transmission and short-term plasticity in Alzheimer’s disease

Authors: ***N. SINGH**, S. NADKARNI;
Biol., Indian Inst. of Sci. Educ. and Res., Pune, India

Abstract: Alzheimer’s disease (AD) is a multifaceted catastrophic disease that involves multiple brain areas resulting in a range of debilitating symptoms that increase in severity over time. The precise molecular mechanisms that underlie the constellation of deficits are not yet known. Early symptoms of AD; the inability to navigate through space and loss of short term memory, suggest that the hippocampal formation is impacted first in the disease. Further, these cognitive deficits precede structural changes in the brain.

Mutations in presenilins 1 and 2 (PS1 and PS2) are implicated in Familial Alzheimer's Disease (FAD). These mutations disrupt calcium homeostasis in cytosol, however the precise mechanism is still not clear. In order to gain a mechanistic understanding of this high-dimensional disease, we focus our investigations on one of the earliest pathological signs, namely, perturbations to intracellular calcium signals within hippocampal synapses. These perturbations modify the plasticity of synapses that ultimately may have a causal link to deficits in cognition.
Our modeling study is carried out in a CA3-CA1 synapse reconstructed from electron microscope images. We simulate signaling pathways relevant to synaptic transmission and short-term plasticity in the presynaptic terminal. We propose that calcium dynamics associated with the endoplasmic reticulum (ER) in the presynaptic terminal accounts for the short-term plasticity profile of the synapse and is essential for normal function. Further, FAD related mutations that compromise the leak channel in the ER, lead to an overload of calcium in the ER, and cause an inordinate increase in cytosolic calcium flux via ryanodine receptors (RyR). The augmented calcium signaling can cause rapid depletion of neurotransmitter vesicles. The contrasting dynamics of increase in release rate of vesicles from a small pool of available vesicles, and, the slow time scales of vesicle recycling, leads to compromised short-term plasticity. Inositol triphosphate receptor (IP_3R) also contributes to cytosolic calcium concentration by releasing calcium from ER in response to certain ionositol triphosphate and calcium concentration. Separately, we also investigate how the changes in binding kinetics and opening rates of IP_3R associated with FAD related mutations in PS, modulate synaptic transmission and other downstream signaling cascades involved in plasticity.

Title: Biochemical and functional deficits in olfactory epithelium and olfactory bulb of 3-5 month old APP/PS1 mice

Authors: *M. CHEN;
South China Normal Univ., Guangzhou, China

Abstract: Olfactory dysfunction is considered as early syndrome of Alzheimer's disease (AD), which occurred before the appearance of learning memory deficits. Therefore, olfactory memory pathway may be the early targets impaired during the onset and progress of AD. In the present study, we observed a significantly reduced electroolfactogram (EOG) amplitude and number of olfactory sensory neurons (OSNs) in the olfactory epithelium of 3-5 months APP/PS1 mice, an age the mice displaying impaired cookie finding ability, compared to wild type (WT) littermate. *In vivo* local field potential (LFP) recording in OB revealed enhanced gamma oscillation power and reduced theta oscillation power accompanied by increased GABA receptor protein levels in APP/PS1 compared to WT mice, indicating that the change of inhibitory GABA signaling may contribute, at least in part, to altered oscillatory activities in OB. The present study suggests that 3-5 months APP/PS1 mice already show impaired olfactory perception, which is earlier than the deposition of Aβ plagues, implying the early dysfunction in olfactory pathway could be concerned as a biomarker for early diagnosis of AD. **Key words:** AD, mature OSNs, $GABA_AR$, electroolfactogram, oscillation. **Acknowlegement:** This work was supported by grants from The National Science Foundation of China (31171018, 31171355), Natural Science Foundation of Guangdong Province (S2011010003403).

Title: Tumor necrosis factor-α mediates LTP impairment in APP/PS1 mice

Authors: *A. SINGH, O. D. JONES, W. C. ABRAHAM;
Dept. of Psychology, Univ. of Otago, Dunedin, New Zealand

Abstract: Alzheimer’s disease (AD) is a neurodegenerative disease and the most common cause of dementia. Synaptic dysfunction and loss in the hippocampus and association cortices are early and characteristic features of AD, and correlated with the severity of cognitive decline. Long-

term potentiation (LTP), an important mechanism underlying learning and memory, is highly regulated by many factors, including the history of prior cell activity (i.e. metaplasticity). Previously we described heterosynaptic metaplasticity in the rat hippocampus in which strong high-frequency priming stimulation in stratum oriens inhibited subsequent LTP elicited in the stratum radiatum of area CA1, an effect mediated by the astrocyte network. Since LTP is inhibited in the APP/PS1 (APP695swe/PS1-dE9) mouse model of AD, we hypothesized that this effect is due to aberrant engagement of this inhibitory metaplasticity mechanism at baseline. To investigate this, acute hippocampal slices were prepared from APP/PS1 and B6C3 wild type mice (12 mo) and field excitatory postsynaptic potentials were recorded from area CA1 following stimulation of Schaffer collateral fibres. The magnitude of LTP was significantly reduced in control transgenic mice (124 $\pm$ 3%, N=7) compared to wild type controls (143 $\pm$ 3%, N=8; $p<0.05$). Priming (6x100 Hz trains) in stratum oriens caused inhibition of radiatum LTP in wild-type mice (126 $\pm$ 2%, N=8) to a level comparable to that of the transgenics (124 $\pm$ 3%, N=7). We hypothesised that release of the cytokine tumor necrosis factor-α (TNF-α) from non-neuronal cells, possibly astrocytes, mediates the inhibition of LTP and that blocking TNF-α would rescue LTP in both the wild-type primed and control transgenic conditions. Primed LTP in wild-type mice was indeed rescued (145 $\pm$ 2%, N=8; $p<0.05$) to control levels by TNF-α antibody preincubation (25 µg/ml). Similarly, the TNF-α antibody rescued non-primed LTP in the transgenic mice (139 $\pm$ 3%, N=7; $p<0.05$) to wild-type levels. These data support the hypothesis that TNF-α mediated inhibition of LTP is aberrantly engaged in AD mice and contributes to the impairments in LTP and cognition seen in this model.

Title: Stability of synaptic proteins in the frontal cortex in the preclinical phase of Alzheimer’s disease

Authors: *M. A. ANSARI[1], S. W. SCHEFF[2];
[1]Sanders-Brown Ctr. on Aging, [2]Univ. of Kentucky Sanders-Brown Ctr. on Aging, Lexington, KY

Abstract: Although the precise etiology of Alzheimer's disease (AD) remains to be elucidated, numerous studies have supported the idea that synaptic dysfunction, in key brain regions, may be a seminal event leading to cognitive impairment. Our previous studies have reported a significant decline in synaptic number and their associated proteins in the hippocampus during the preclinical progression of the disease. The hippocampus is one of the earliest brain regions affected, and the loss of synaptic proteins strongly correlates with numerous markers of oxidative stress. As the disease progresses, oxidative stress increases in other brain regions such as frontal cortex (Brodmann area 9). In the early stages of the disease, there are significant changes in various enzymatic and non-enzymatic markers of oxidative stress in the frontal cortex. This study was designed to test whether or not levels of synaptic proteins are altered in the frontal cortex in the very early (preclinical) phase of AD similar to that observed in the hippocampus. We analyzed short post-mortem tissues obtained from different cohorts: (1) individuals with low or no AD-type pathology and no cognitive impairment (LP-NCI), (2) individuals with high AD-type pathology and no cognitive impairment (HP-NCI), and (3) individuals with amnestic mild cognitive impairment (aMCI). Possible changes in both pre-synaptic (synapsin-I and synaptophysin) and post-synaptic (drebrin and PSD-95) proteins were analyzed in all age matched subjects. The results showed a stability of synaptic proteins in the frontal cortex in the early stages of the disease. These results support the idea that the frontal cortex, although affected late in the disease progression, remains unaffected in the preclinical stage. The hippocampus may be more sensitive than other brain regions during the early stage, and future therapeutic interventions should concentrate on this area.

Title: Formation and repair of DNA double-strand breaks in neurons: implications for Alzheimer's disease and related disorders

Authors: *M. D. EVANS[1,2], D. CHENG[1], L. MUCKE[1,2];
[1]Gladstone Inst. of Neurolog. Dis., San Francisco, CA; [2]Dept. of Neurol., Univ. of California, San Francisco, San Francisco, CA

Abstract: In *postmitotic* cells, the maintenance of genomic integrity is crucial to prevent the activation of cell death programs such as apoptosis. This is arguably most important for neurons, because the majority of these cells cannot be replaced during adulthood. We recently made the surprising discovery that the most severe form of DNA damage, double-strand breaks (DSBs), occurs in neurons of wildtype mice as a result of physiological and experimentally induced brain activity, for example, engagement of different brain regions during exploratory behavior. These activity-induced DSBs are repaired within hours. However, in human amyloid precursor protein (hAPP) transgenic mice from line J20, which simulate key aspects of Alzheimer's disease, the baseline levels of DSBs are increased, most likely due to deficient DSB repair involving depletion of the DNA repair protein breast cancer factor 1 (BRCA1). Independent lines of evidence suggest that activity-induced DSBs may be involved in the regulation of neuronal gene expression and the creation of neuronal diversity.
The mechanisms underlying the formation and repair of neuronal DSBs in health and disease are not fully understood. To facilitate the investigation of these mechanisms, we developed a neuronal culture assay that allows for rapid post-hoc imaging and unbiased quantification of DSBs in thousands of cells. We have coupled this technique with combinatorial immunocytochemistry, enabling the identification of DSBs in multiple cell types including dentate granule cells, CA pyramidal neurons and inhibitory neurons, as well as glial cells. Using this technique, we have confirmed that neuronal activation causes DSBs and identified baseline differences in the levels of activity-induced DSBs across different cell types. We also found that such DSBs, as defined by γH2A.X immunofluorescent punctae, are efficiently repaired within 3 hours. We are currently using this methodology to explore the role of DSBs and BRCA1 in neuronal functions and integrity.

Title: The role of Drp1 in AMPAR trafficking and Alzheimer's disease

Authors: *M. J. HEIMANN[1], C. S. BINDA[1], E. BRAKSATOR[2], C. GUO[1], K. A. WILKINSON[1], J. M. HENLEY[1];
[1]Dept. of Biochem., [2]Dept. of Physiology, Pharmacol. and Neurosci., Univ. of Bristol, Bristol, United Kingdom

Abstract: Alzheimer's disease (AD) is a neurodegenerative disease in which mitochondrial and synaptic dysfunction, as well as aberrant α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (AMPAR) trafficking and synapse loss, are major factors in the manifestation and progression of the disease. It has been reported that dysregulation of the post-translational modification SUMOylation plays a role in the characteristic cognitive deficits observed in AD. Therefore we systematically analysed protein levels of the three Small Ubiquitin-like MOdifier paralogues SUMO1-3, SUMOylation pathway enzymes and known SUMO substrates in human AD *post mortem* brain tissue obtained from the South West Dementia Brain Bank by western blotting. We observed a decrease in protein level of the SUMO substrate dynamin-related protein 1 (Drp1) in Brodmann area 10 (BA10), a region in the prefrontal cortex severely affected by the disease, but not in cerebellum, a region largely spared by the disease, indicating a disease-specific reduction of Drp1. Drp1 is a mitochondrial GTPase required for fission and it plays an important role in synaptic function, structure and synaptic development. We then sought to examine the role of Drp1 and Drp1 SUMOylation in AMPAR trafficking and whether Drp1 reduction contributes to the synaptic dysfunction observed in AD. Lentivirus-mediated knockdown of endogenous Drp1 in primary cortical neurons followed by surface biotinylation and western blotting showed that loss of Drp1 leads to a significant decrease of surface, but not total, levels of the AMPA receptor subunits GluA1 and GluA2 under basal conditions. However, chemically induced long-term depression (chemLTD) via bath application of N-methyl-D-aspartate (NMDA) showed that Drp1 knockdown does not occlude the initial internalisation of surface GluA2 characteristic of chemLTD. These results suggest that Drp1 plays a role in AMPAR trafficking under basal conditions. We are now investigating whether the observed reduction of surface GluA1 and GluA2 is caused by synapse loss, a major correlate of the cognitive decline in AD, using electrophysiology and immunocytochemistry. Furthermore we are using a lentivirus-mediated knockdown and rescue approach to examine the role of Drp1 SUMOylation in mediating its effects on AMPAR trafficking. Together, our data indicate that Drp1 function is perturbed in AD, potentially contributing to the aberrant AMPAR trafficking and synaptic dysfunction observed in the disease, and highlight Drp1 as a possible therapeutic target.

Title: Early life stress worsens cognitive performance, synaptic plasticity and Aβ levels in APP/PS1 mice

Authors: *S. L. LESUIS, B. A. C. E. VAN HOEK, P. J. LUCASSEN, H. J. KRUGERS;
Ctr. for Neurosci., Univ. Van Amsterdam, Amsterdam, Netherlands

Abstract: Ample evidence has indicated that dysregulation of the hypothalamic-pituitary-adrenal (HPA) axis, which controls circulating levels of glucocorticoid (GC) hormones, occurs early in Alzheimer's Disease (AD). Elevations in GCs have been reported to increase Aβ formation and augment tau phosphorylation and accumulation, consistent with the hypothesis that high levels of GCs, as found in AD, may play a central role in the development and progression of AD.
Lasting alterations in HPA axis responsiveness and GCs are, at least in part, determined by experiences during the early postnatal period. Early life stress (ELS) increases later HPA axis responsiveness and GC levels, which accompany cognitive decline. Therefore, in this study we investigated whether and how early life stress can accelerate the development of AD pathology. Male WT and APP/PS1 mice were housed with limited nesting and bedding material from PND 2-9 (ELS). HPA axis responsivity, Aβ levels, synaptic plasticity and cognitive performance were assessed in animals aged 4-6 months and 10-12 months.
We show that APP/PS1 mice exposed to ELS have a higher stress reactivity compared both to control-reared transgenic mice and wild type ELS mice. These effects were accompanied by *enhanced* levels of soluble Aβ-related, both in 6 and 12 months old mice. In ELS APP/PS1 mice, synaptic plasticity of the hippocampal CA1 area was strongly and persistently *increased* from an early age onwards. Finally, spatial memory performance as assessed in the Barnes Maze was *impaired* in 12 month old APP/PS1 mice that were exposed to ELS. WT animals exposed to ELS and transgenic mice showed reduced levels of conditioned fear in an auditory fear conditioning task. Interestingly, conditioned fear responses were *increased* in transgenic ELS mice.
These studies indicate that early life adversity determines stress-responsiveness, synaptic plasticity and cognitive performance in mice with a relevant mutation for AD. Further understanding of the mechanisms underlying cognitive alterations in APP/PS1 mice as a consequence of early life stress will yield valuable insights on how adverse events determine the progression of AD.

Abstract: Alzheimer's disease (AD) is the most common type of dementia, caused by degeneration of brain regions involved in memory and cognition. Early stages of the disease are characterized by synaptic dysfunctions and synapse loss, which correlate with the severity of memory loss in patients. So far, no effective cure for AD exists with current treatments mainly focusing on increasing the quality of life of patients. EphA4 is a tyrosine kinase receptor of the ephrin system mainly expressed in the hippocampus and cerebral cortex during adulthood. It is involved in the regulation of synaptic maintenance and plasticity. EphA4 activation results in downregulation of AMPA receptors, loss of synaptic glutamate transporters and retraction of dendritic spines. In amytrophic lateral sclerosis we demonstrated that EphA4 is involved in axonal regeneration capacity. Based on these various functions, we hypothesized that EphA4 ablation might mediate synaptic dysfunction and consequently cognitive performance in a mouse model of AD. We conditionally deleted EphA4 in the forebrain of APPPS1-21 mice. This mouse model is characterized by extensive amyloidosis of the brain, resulting in synaptic dysfunctions and cognitive deficits around the age of 9 months. To investigate the effect of EphA4 deletion on cognitive function, we performed a battery of behavioral tests, including the open field,

sociability/preference for social novelty, Morris water maze and contextual fear conditioning. Together, our results suggest an effect of EphA4 in ameliorating the cognitive deficits in this AD mouse model. Ongoing molecular analysis of amyloidosis and synaptic function will allow dissection of the underlying processes that have shown to improve cognitive defects.

Research, Univ. of Edinburgh, Edinburgh, United Kingdom; [6]Dept. of Neuroscience, Ctr. for the Cell. Basis of Behaviour, Inst. of Psychiatry, King's Col. London, London, United Kingdom

Abstract: Synapses are an early pathological target in a wide range of neurodegenerative conditions including well known adult onset Alzheimer's, Parkinson's & Huntington's disease [1-3] and diseases of childhood such as the motor neurone disease - Spinal Muscular Atrophy and the neuronal ceroid lipofuscinoses (NCL's; A.K.A Batten disease) [4-6]. However, our understanding of the mechanisms regulating the stability of synapses and their exceptional vulnerability to neurodegenerative stimuli remains in its infancy.
To address this we are using the NCL's as a tool to identify novel regulators of synaptic stability, contributing to our understanding of a broad range of diseases and highlighting novel therapeutic

targets. The NCLs, are the most frequent autosomal-recessive disease of childhood [7]. There are currently 14 individual genes which mutations are capable of affecting lysosomal function, all of which result in similar phenotype including blindness, cognitive/motor deficits, seizures and premature death. Mutations in CLN3 underlie a juvenile form of NCL (JNCL), the most prevalent variant worldwide [8]. Differential vulnerability of distinct synaptic populations across different brain regions has been described in other models of NCL variants [5, 6] but not yet in JNCL. Here, we describe a similar pattern of synaptic loss in the Cln3 null mouse model of JNCL (*Cln3*$^{-/-}$). Secondly, we use this differential pattern of synaptic loss to map molecular expression profiles across three brain regions. Thirdly, this region vulnerability expression mapping revealed conserved molecular alterations between JNCL and other neurodegenerative conditions [9]. Finally, we demonstrate that genetic and/or pharmacological manipulation of candidate expression in *Drosophila* is sufficient to modulate disease progression *in-vivo*.

Abstract: Cholinesterase inhibitors and the N-methyl D-aspartate (NMDA) glutamate receptor inhibitor are the currently approved agents for the symptomatic treatment of dementia associated with Alzheimer's disease (AD). Memantine added to stable donepezil in AD patients is associated with significant benefits in reducing decline in cognition, function and global status. However, the improvement is modest. Blocking or negatively regulating the functions of histamine-3 (H3) receptor is currently being explored as a potential symptomatic treatment for AD. SUVN-G3031 is a potent and selective H3 receptor inverse agonist. We hypothesized that SUVN-G3031 may potentiate the therapeutic effects of memantine and donepezil. Hence, the effect of SUVN-G3031 in combination with memantine and donepezil was evaluated in object recognition task. The effect of the above combinations on the cholinergic neurotransmission was evaluated in the hippocampus of freely moving male Wistar rats using brain microdialysis and the effect on theta oscillation in hippocampus was measured using EEG in anesthetized rats. Co-treatment of SUVN-G3031 with memantine and donepezil significantly potentiated the procognitive effects when compared with memantine and donepezil treatment group. Similarly co-treatment of SUVN-G3031 with memantine and donepezil significantly enhanced the acetylcholine levels and theta oscillatory activity in the hippocampus. The enhanced procognitive effects seen in the group co-treated with SUVN-G3031, memantine and donepezil can be attributed to the augmentation of the cholinergic neurotransmission in the brain. Thus combination of SUVN-G3031 with memantine and donepezil may offer a new therapeutic strategy for the symptomatic treatment of Alzheimer's disease.

Title: Grx1 over-expression reverses spine loss in primary cortical neurons derived from Alzheimer's disease transgenic mice.

Authors: *D. DAS[1], R. P. KOMMADDI[1], A. RAY[1], B. L. SCHNEIDER[2], P. AEBISCHER[2], V. RAVINDRANATH[1];

Abstract: $A\beta_{42}$, one of the major causative agents implicated in Alzheimer's disease (AD), is known to directly and indirectly generate reactive oxygen species (ROS) leading to oxidative stress. Perturbation of redox homeostasis contributes considerably to the pathogenesis of AD. This is presumably due to the fact that the brain is not well equipped with anti-oxidant defense mechanisms. Glutathione, the ubiquitous antioxidant, is present in smaller quantities in the brain compared to the periphery, rendering the brain more susceptible to oxidative stress. Oxidative stress adversely impact neuronal function by altering protein structure and function through mechanisms including sulfoxidation, glutathionylation, nitrosylation and carbonylation. Glutathionylation is a common downstream effect of oxidative stress, and glutaredoxin 1 (Grx1), a thiol disulfide oxidoreductase, catalyzes the reversal using reducing equivalents of glutathione. We used primary cortical cultures from the APP^{Swe}/PSEN1ΔE9 transgenic mice as an AD model system to study the role of oxidative stress in triggering structural changes in neurons. We measured changes in area of soma, total length and branching of neurites, and spine density. Interestingly, significantly higher levels of ROS were detected in both soma and neurites of transgenic neurons at 15 *days-in-vitro* (DIV). This corresponded with a significant loss in density of total and mushroom spines, starting at DIV-15, persisting upto DIV-21, while other morphological changes were only detected at DIV-21. This suggests that spine loss could potentially be one of the early structural changes downstream of oxidative stress. Mushroom spines are involved in formation of synapses, and a loss in these structures indicates functional impairments in neurons. In order to ascertain the contribution of ROS-dependent protein glutathionylation towards spine loss observed, we over-expressed Grx1 neurons and found that it rescued total and mushroom spine loss seen in these neurons. In conclusion, at least one of the mechanisms through which $A\beta_{42}$ triggers spine loss is via increased oxidative stress, resulting in glutathionylation of target proteins.

Title: Activity and levels of calpain 2 but not calpain 1 is upregulated in synaptosomes early in the pathogenesis of Alzheimer's disease

Authors: *F. AHMAD[1], D. BENNETT[2], V. RAVINDRANATH[1];
[1]Indian Inst. of Sci., Bangalore, India; [2]Rush Univ. Med. Ctr., Chicago, IL

Abstract: The pathogenic mechanisms underlying Alzheimer's disease (AD) are now known to include synaptic dysfunction even in early stages of AD when there is little β-amyloid deposition or neuronal death. While, synaptic dysfunction in AD is associated with multiple mechanisms including disrupted Ca^{2+} homeostasis, oxidative stress and mitochondrial dysfunction, the molecular players are largely unknown. Calpain, a calcium dependent, non-lysosomal cysteine protease plays a critical role in synapse function and plasticity. However, dysregulated global hyperactivation of calpain is implicated in neuronal death in various models of neurodegeneration, including AD models, late in the disease process. Since calpain plays an important role in normal synapse function, we sought to examine whether dysregulation of calpains contributes to early synaptic dysfunction in AD pathogenesis. To this end, we analyzed the expression profiles of two major brain isoforms of calpain; calpain 1 and 2 in synaptosomes and post nuclear supernatant (PNS) isolated from cortices of both young pre-symptomatic (1 and 3 months old) and middle aged symptomatic (9-12 months old) APPswe/PS1ΔE9 (APP/PS1) mice, a well established mouse model of AD. While expression of both calpain 1 and 2 were unaffected in PNS of APP/PS1 mice, we observed increased expression of calpain 2 in synaptosomes as early as 3 months of age that persisted up to 9-12 months of age. Importantly, activity of calpain 2 in synaptosomes was upregulated from 1 month onwards and persisted up to 9-12 months. Interestingly, calpain 1 expression was unaffected in synaptosomes of APP/PS1 mice at pre-symptomatic ages of 1 and 3 months of age and increased only at 9-11 months of age when overt behavioral and pathological symptoms are evident. Moreover, we observed increase in protein and activity levels of calpain 2 in synaptosomes isolated from post mortem frontal neocortical tissue of persons with AD compared to persons without cognitive impairment. Additionally, increase in synaptosomal calpain 2 activity significantly correlated with decline in

performance of in memory and cognitive tests as wells as increase in β-amyloid load. To our knowledge, this is the first study reporting synapse specific calpain 2 hyperactivation in APP/PS1 mouse model during an early presymtomatic age as well as in post mortem brains of persons with AD. This is interesting in view of findings from genetic studies confirming that calpain 2, but not calpain 1, is indispensible for synapse function and plasticity.

Title: Structural changes in CA1 hippocampal neurons in adolescent Alzheimer's disease transgenic (APP^{Swe}/PSEN1ΔE9) mice.

Authors: *S. KUMAR, V. RAVINDRANATH;
Ctr. for Neurosci., Indian Inst. of Sci., Banaglore, India

Abstract: Alzheimer's disease (AD) is a progressive neurodegenerative disease characterized by decline in cognitive functions, including memory impairment. Synapse loss is considered to be an early event in AD pathogenesis. We examined spine density and structural changes in neuronal morphology in a mouse model of Alzheimer's disease using APP^{Swe}/PS1ΔE9 (APP/PS1) mice. Although spatial memory impairments are observed at 9 months of age in this mouse model, we hypothesized that structural changes including density of different subclasses of spines could precede these defects and arise early. Brains from 1 month and 18-21 months old APP/PS1 mice (wild-type and transgenic) were fixed for Golgi staining and 100 μm serial sections were cut for spine and morphometric analyses. The hippocampal CA1 region was chosen for this study. Interestingly, we observed for the first time tertiary apical dendritic spine loss, including reduction in mushroom spine density, as early as 1 month of age. This progresses during life-span extending to spine loss on secondary dendrites, seen as loss of mushroom and stubby spines, at 18-21 months of age. Interestingly, Sholl analysis also revealed limited morphological changes in apical arborization in 1 month APP/PS1 mice. These changes extended to both apical and basal arborization in 18-21 months old animals., Thus, our study

demonstrate that AD-relevant pathological changes affecting neuronal structural features start early and progress with increasing age, with spine loss as one of the earliest events.

Title: Histological evaluation of synaptic markers in animal models of alzheimer's disease

Authors: ***J. NEDDENS**[1], M. ZHAN[2], E. AUER[1], B. HUTTER-PAIER[1];
[1]Neuropharm., QPS Austria GmbH, Grambach, Austria; [2]Biomed. Sci., Univ. of Applied Sci., Graz, Austria

Abstract: Alzheimer's disease (AD) is an age-dependent neurodegenerative disorder that represents the most common dementia worldwide. The histopathological hallmarks of this disease are accumulation of ß-amyloid (Aß) both within neurons, and extracellular as senile plaques, and intracellular formation of neurofibrillary tangles (NFT) consisting of hyperphosphorylated tau. These pathologies often affect synaptic function and can result in neuronal loss. Transgenic animal models are frequently used to test new compounds against AD and should thus mimic the most common disease pathologies. To investigate synaptic changes in different AD rodent models, we used two synaptic markers, synaptophysin and spinophilin, to quantify the synapse density in the hippocampus. synaptophysin represents a presynaptic protein, which is most commonly used to quantify synapses. By contrast, spinophilin a postsynaptic protein, which is specifically located on dendritic spines, is used to visualize spine density. Five different rodent models were analyzed: transgenic APPsi, TauP301L and double-transgenic APPsi x TauP301L rats as well as transgenic TBA2.1 and APP_{SL} mice. Our results show that hippocampal synaptophysin was significantly increased in all three transgenic rat models, while spinophilin levels did not change. APP_{SL} transgenic mice showed a progressive increase of synaptophysin in the hippocampal CA1 region while spinophilin was only increased at the age of 12 months. Further analyses of TBA2.1 mice did not result in any significant changes. Our results show that in most transgenic AD rodent models the presynaptic marker synaptophysin is strongly altered while the postsynaptic marker spinophilin is almost not changed, suggesting a disturbed synapse formation in transgenic AD rodent models.

Abstract: Of the main pathological features of Alzheimer's disease (AD), synapse loss is the greatest correlate of clinical cognitive decline, and this synapse loss is thought to be central to disease pathogenesis. Although most cases of AD are not directly heritable, genetic risk factors have been identified, the strongest of which is the epsilon 4 isoform of Apolipoprotein E (ApoE4). The ApoE4 allele increases not only the chance of developing AD compared to the more common ApoE3 allele but also increases the rate of cognitive decline seen within the disease. The ApoE4 allele has been shown to affect the synaptic plasticity and cognition of APOE4 carriers without AD. However the mechanisms by which AD causes synaptic degeneration and the role that ApoE4 plays in that degeneration remains unclear.
Proteomic analysis of synaptoneurosomes isolated from 25 control and 30 Alzheimer's disease patients with known APOE genotypes have indicated that 241 proteins were changed in the AD synapse samples compared to control. IPA analysis of these proteins found that the top affected pathways were mitochondrial dysfunction, lipid metabolism and oxidative phosphorylation. A subset of proteins changed between control and AD were also found to be changed in the same direction when AD ApoE3 cases were compared with AD ApoE4 cases. The top affected pathways of this subset were lipid transport, ion binding and the immune system. This group of proteins included clusterin and complement C4, both of which also have been genetically linked to AD. Once validated by fluorescent western blot, these protein hits have been further investigated using array tomography in postmortem human brain tissue to assess their contribution to synapse loss.
This study reveals new proteins and pathways that may be involved in synapse degeneration in AD and highlights the role genetic risk factors in this process.

Title: Processing bodies and oAB-induced synaptic mRNA dysregulation

Authors: C. WILLIAMS[1], S. MARQUEZ-VILENDRER[2], M. A. ROOF[1], S. SHETTY[1], *C. A. MILLER[3];
[1]Dept. of Pathology, Keck Sch. of Med. of USC, Los Angeles, CA; [2]Axogen Inc, Alachua,, FL; [3]Dept Pathol, USC, Los Angeles, CA

Abstract: Plasticity, memory encoding and consolidation are dependent on local protein synthesis, initiated and regulated at the synapse. Interactions of oligomeric ß-amyloid (oAβ) with synapses may modify mRNA targeting, transport and stability. Our previous results show that some mRNAs, translated at the synapse, are increased in early Alzheimer's Disease. One potential mechanisms is perturbation of intraneuronal granule-like droplets that sequester and stabilize mRNAs for degradation or translation, the processing bodies (PB's) and stress granules (SG's), respectively. We investigated effects of chronic, non-toxic doses of oAß on PB's and SG's in soma and dendrites of primary dissociated, or organotypic cultures of rat frontal cortex, and in 5xFAD transgenic mice. Cultures were prepared and incubated for 7 days in medium prior to addition of oAß or scrambled oAß (sAß) then maintained, with 3-4 day refeeding for 14 days. Cultures were harvested at 7 and 14 days and prepared for immunostaining or immunoblotting using antibodies for SG protein, elF3ß; PB protein, DDX6; and the mRNA-binding proteins FMRP and CPEB. Primary cultures were also probed for protein synthesis products using Click-iT® to reveal effects of oAβ on translation. Confocal imaging and analysis using ImageJ revealed a change in number, and in the size ratio of PB's in treated primary cultures. PB's were increased in somas and proximal dendrites of oAß-treated cultures after 7 days compared to control, whereas SG's were maintained at a low level in both. FMRP, a translational repressor, was depleted in neurites of treated cultures, whereas CPEB, a translation activator, appeared more abundant and present in puncta adjacent to sites of translation. However, oAβ did not

induce a significant increase in protein synthesis. Results from oAß-treated organotypic cultures also show enhanced PB droplet formation and concomitant increase in DDX6 protein after 7 and 14 days exposure. In addition, PB's were more widely distributed in cortical neuropil of 3 month old 5xFAD mice compared to controls. DDX6 is present in PB's containing stalled polysomes and thus an increase in DDX6 containing droplets in oAß treated cultures, and in 5xFAD mice, suggests that oAß may encourage mRNA silencing. However, as oAβ apparently fails to reduce protein synthesis in dendrites, a select group of mRNAs may be targeted to PB's whilst others are freely translated.

Title: Identification of drug candidates that block the effects of alpha-synuclein oligomers on membrane trafficking

Authors: C. SILKY[1], *R. YURKO[2], K. MOZZONI[1], C. REHAK[1], N. IZZO[1], G. RISHTON[1], G. LOOK[1], H. SAFFERSTEIN[1], S. M. CATALANO[1];
[1]Cognition Therapeut. Inc, Pittsburgh, PA; [2]Cognition Therapeutics, Inc, Pittsburgh, PA

Abstract: Parkinson's disease (PD) is a neurodegenerative disease characterized by dysfunction in motor control as well as non-motor symptoms and cognitive loss. While motor symptoms are currently addressed by therapeutics, cognitive deficits are not, and represent a huge unmet medical need for PD patients. These cognitive deficits may be caused by oligomeric forms of alpha-synuclein (Asyn) protein that inhibit SNARE mediated vesicle fusion (Choi '15), disrupt

synaptic plasticity and impair long-term potentiation (Diogenes ’12; Martin ‘12). We have developed a screening assay capable of measuring Asyn oligomer-induced changes in membrane trafficking rate in primary neuronal cultures 21DIV (z’ score= 0.91). This assay thus provides a disease-relevant measure of Asyn oligomer neuronal deficits related to the cognitive deficits observed in Parkinson’s disease, and can be used to identify potential therapeutics capable of blocking Asyn-induced trafficking deficits (Danzer ’09).
Oligomers of full length recombinant Asyn closely match those isolated from human PD patient brain (see accompanying abstract) and both human PD patient-derived and recombinant Asyn oligomers cause deficits in membrane trafficking rate. Preliminary screening of the NIH Small Molecule Repository has identified several compounds that reverse effect of recombinant Asyn oligomer by >80% while having no effect on membrane trafficking when dosed on their own, including FK-506, phenothiazine, and hyperoside. These compounds have been previously implicated in Parkinson disease research or relevant disease pathways (Perren et al. 2015; Ye et al. 2014; Zhang et al. 2014), validating the ability of this screening platform to identify PD-relevant therapeutic leads.

Title: Structure of the N-terminal region of alpha-synuclein determines the rate of fibril growth

Authors: D. D. DHAVALE, C. TSAI, D. P. BAGCHI, L. A. ENGEL, J. SAREZKY, *P. T. KOTZBAUER;
Neurol., Washington Univ., Saint Louis, MO

Abstract: The accumulation of alpha-synuclein (α-syn) fibrils is the defining pathologic process in Parkinson disease (PD). A pathogenic role for α-syn is supported by the identification of dominantly inherited α-syn (*SNCA*) gene mutations in rare familial PD. Fibril formation requires an initial nucleation event to produce seeds, followed by fibril growth, during which monomeric protein associates with existing seeds. To characterize fibril formation kinetics, we produced recombinant α-syn protein containing an N-terminal bicysteine tag (C2-α-syn), which enabled detection of both soluble oligomers and mature fibrils with fluorescein arsenical hairpin (FlAsH) dye. In seed growth by monomer association (SeGMA) assays measuring fibril growth in the presence of C2-α-syn monomer, some PD-associated α-syn mutations (H50Q and A53T) greatly increased growth rates, while other mutations (E46K, A30P and G51D) decreased growth rates. We also measured the growth of WT seeds extended by mutant monomer or mutant seeds extended by WT monomer, since interactions between mutant and WT α-syn proteins could also influence fibril accumulation in familial PD. We found that single amino acid differences between seed and monomer protein sequences consistently decrease growth rates. These results demonstrate that the rate of α-syn monomer association during fibril growth is highly dependent on alignment of the N-terminal region of α-syn polypeptide chains, and that only a subset of familial PD mutations causes fibril accumulation through increased fibril growth rates. SeGMA assays can be utilized to further elucidate structural requirements of fibril growth and to identify inhibitors of this process as a potential therapeutic approach in PD.

Title: HA53T-α-syn accumulation and associated neurotoxicity is prevented by the inhibition of mitochondrial fission

Authors: *S. BIDO[1], R. FAN[2], K. TIEU[2], E. BEZARD[1];
[1]CNRS UMR 5293, Inst. des Maladies Neurodégénératives, Bordeaux, France; [2]Plymouth Univ., Plymouth, United Kingdom

Abstract: Post-mitotic cells such as neurons have to deal with toxic insults for the entire life span. The only way to survive is to maintain a really efficient clearance system to preserve the integrity of energetic balance. In Parkinson's disease (PD), genetic mutations can have detrimental effects on clearance machinery leading the accumulation of dangerous reactive species of which the most representative is α-synuclein (α-syn). The accumulation causes the impairment of mitochondrial functionality with the consequent drop in energy production inducing neuronal death. In this study we demonstrate the mutual relationship between α-syn accumulation and mitochondrial functions and the possibility to reduce neurodegeneration when acting on mitochondrial phenotype. Firstly we assessed the impact of the overexpression of the pathogenic human A53T-α-syn (hA53T-α-syn) on mitochondrial morphology. hA53T-α-syn-overexpressing neurons showed a shift of mitochondrial network toward a less elongated phenotype, associated with the impairment of mitochondrial functionality (membrane potential and spare respiratory capacity) both in vitro and in vivo. Confirming a previous work (Bourdenx et al., 2015), we observed neuronal loss in rats overexpressing the hA53T-α-syn in SNc. In addition we also found a significant accumulation of PK-resistant hA53T-α-syn aggregates. Based on these results we decided to evaluate the efficacy of a neuroprotective strategy aimed to modify the mitochondrial dynamics by reducing fragmentation. To that end, we used the small molecule mdivi-1 (Rappold et al., 2014), a selective inhibitor of the dynamin-related protein 1 (drp1), the major player in mitochondrial fission events. Mdivi-1 reestablished the normal mitochondrial phenotype and functionality both in cells and rats. Moreover the rescue of anormal mitochondrial morphology is followed by a significant neuroprotectection. Furthermore we observed a decrease inw PK-resistant and phosphorylated hA53T-α-syn in SNc. These results

suggest that the mitochondrial fate is tightly linked with the accumulation of the pathogenic forms of hA53T-α-syn and vice versa. A possible explanation is the generation of an amplification loop that begins with the translocation of drp1 on mitochondrial membrane caused by the accumulation of hA53T-α-syn (Guy et al., 2012). This is followed by the enhancement of mitochondrial fragmentation that in turn can have a worsening effect on cellular clearance machinery. The treatment with the fission inhibitor mdivi-1 is able to preserve the integrity of mitochondria thus breaking down the vicious circle.

Title: 14-3-3s reduce endogenous alpha-synuclein aggregation and toxicity induced by fibrillary alpha-synuclein

Authors: R. UNDERWOOD[1], B. WANG[1], *T. A. YACOUBIAN[2];
[1]Neurol., Univ. of Alabama at Birmingham, Birmingham, AL; [2]Dept Neurol, Univ. Alabama Birmingham, Birmingham, AL

Abstract: Alpha-synuclein (αsyn) plays a critical role in Parkinson's disease (PD). Recent research suggests a prion-like mode for αsyn toxicity: αsyn is released as aggregated species that cause further aggregation and toxicity in neighboring cells. We have been investigating the role of the 14-3-3 proteins in regulating αsyn propagation. 14-3-3s are chaperone-like proteins that reduce protein aggregation, regulate protein secretion, and promote cell survival. To examine the effect of 14-3-3s on αsyn propagation, we employed an αsyn fibril model. Treatment of primary hippocampal cultures with recombinant αsyn preformed fibrils has been shown to cause misfolding and aggregation of endogenous αsyn. Here we demonstrate that endogenous 14-3-3s are sequestered with S129-phosphorylated αsyn into insoluble aggregates: in PBS-treated cultures, immunocytochemistry using an antibody against all 14-3-3 isoforms shows diffuse staining throughout the cell body and neurites, but as early as seven days after treatment with αsyn fibrils, 14-3-3 staining colocalizes with S129-phosphorylated αsyn. Since 14-3-3s can regulate αsyn aggregation, we next tested whether overexpression of 14-3-3θ can reduce aggregation of endogenous αsyn upon αsyn fibril treatment in this model. Day *in vitro* (DIV5)

primary cultures from nontransgenic and transgenic mice that overexpress HA-tagged14-3-3θ under the Thy1.2 promoter were treated with PBS or αsyn fibrils at 0.5 or 1 μg/ml, and then stained for S129-phosphorylated αsyn at 7, 10, and 14 days after fibril treatment. We observed ~70% decrease in insoluble phospho-S129 αsyn staining at 7 days after treatment with both doses. This reduction persisted at 14 days after treatment, with a reduction in phospho-S129 αsyn staining by 71% with 0.5 μg/ml fibril dose and by 61% with 1 μg/ml fibril dose in 14-3-3θ cultures compared to cultures from nontransgenic littermates. In concert with reduced phospho-S129 staining in 14-3-3θ cultures, we also observed a reduction in neuron loss at 14 days after fibril treatment. We are now examining αsyn aggregation and toxicity in primary cultures from nontransgenic and transgenic mice expressing the pan 14-3-3 peptide inhibitor difopein. We have also initiated pilot studies *in vivo* in which PBS or αsyn fibrils were stereotactically injected into the cortex of nontransgenic or 14-3-3θ transgenic mice. Based on these findings, we conclude that 14-3-3θ can regulate the propagation of αsyn and may serve as a target for therapeutic intervention in Parkinson's disease.

Title: Structural elucidation of alpha-synuclein oligomers using a library of sequential antibodies

Authors: *L. NILSSON[1], T. ISLAM[2], A. OLOFSSON[2];
[1]Dept. of Chem., Umea, Sweden; [2]Dept. of medical biochemistry and biophysics, Umea, Sweden

Abstract: Misfolding and aggregation of the presynaptic protein alpha-synuclein (asyn) into amyloid fibrils is associated with Parkinson's disease (PD). It is increasingly accepted that it is the prefibrillar forms of asyn, the oligomers, that are the most toxic specie of the aberrantly folded asyn. Structural information about the oligomers is however scarce due to their transient

nature and their tendencies to aggregate. Using a library of peptide antibodies, spanning the sequence of asyn, we can uncover regions in the oligomers that differ in exposure when comparing with the monomer and with the help of an oligomeric-specific antibody we are able to capture oligomers from complex samples. By comparing the pattern of exposure we can acquire a fingerprint of an oligomer and reveal structural differences between oligomers formed under different conditions. Understanding the structure of the oligomeric species is vital for the development of effective therapeutics against this toxic specie.

Title: Multimer-PAGE reveals shift from multimeric to monomeric α-synuclein in HEK293 cells overexpressing A53T mutant α-synuclein

Authors: *B. A. KILLINGER, D. YEDLAPUDI, A. MOSZCZYNSKA;
Dept. of Pharmaceut. Sciences, EACHPS, Wayne State Univ., Detroit, MI

Abstract: The aberrant aggregation of α-synuclein is a key factor in Parkinson’s disease (PD). In vivo, α-synuclein likely exists in equilibrium between a monomer and several multimers. Studies suggest that a deficit in α-synuclein multimer formation is an initiating factor for its aberrant aggregation. Several α-synuclein mutations, including A53T, may impair α-synuclein multimer formation. Recently we described an analytical technique, termed multimer-polyacrylamide gel electrophoresis (multimer-PAGE), which allows for determination of α-synuclein multimer stoichiometry in brain tissue lysates. However, it remains unclear how this technique could be applied to disease models. Here we used multimer-PAGE to describe α-synuclein multimer stoichiometry in HEK293 cells overexpressing A53T mutant α-synuclein. Results show that wildtype (WT) α-synuclein, when overexpressed, displays a slight shift from multimer to monomer. In contrast, A53T overexpressing cells show a marked shift from the α-synuclein multimer to monomer. The shift from multimer to monomer in A53T overexpressing cells was not due to differences in transfection efficacy. Through further validation of multimer-PAGE, we also showed that the measured ratios were constant regardless of protein input and that binding efficacy of α-synuclein during the protein transfer likely explains why protein input was directly

proportional to the observed ratio of multimer to monomer. In conclusion, multimer-PAGE confirmed the shift in α-synuclein multimer to monomer as a possible disease initiating step in PD.

Title: A high throughput screening system for visualizing therapeutic drugs of neurodegenerative diseases

Authors: ***S. L. WALKER**[1], D. C. W. CHAN[2], V. C. T. MOK[3], W. H. YUNG[2], Y. KE[2]; [1]The Chinese Univ. of Hong Kong, Shatin, Hong Kong, Hong Kong; [2]Sch. of Biomed. Sci., [3]Dept. of Med. and Therapeut., The Chinese Univ. of Hong Kong, Shatin, Hong Kong

Abstract: Brain diseases including neurodegenerative disorders pose one of the major challenges to the health care system worldwide particularly in regions, such as Hong Kong, that are facing a rapidly aging population. Development of new, more effective drug treatments to cope with neural diseases is a burning issue. However, current drug screening systems and procedures, especially for those targeting brain diseases, have severe limitations. To identify novel therapeutics, we have designed an in vivo imaging system which integrates behavioral dynamics of zebrafish, microfluidic devices, OLEDs, and multiphoton imaging into a robust imaging platform. Utilizing a preliminary design of this system, we were able to capture larvae zebrafish in a transferable microfluidic device, position under a multi-photon microscope for in vivo calcium imaging in the presence of a red light stimulus. This method was able to statistically and reproducibly differentiate between epileptic and healthy, Parkinson's and healthy, and their respective treatments in zebrafish larvae. In vivo neural imaging provided an avenue for distinguishing differences between currently available therapeutic drugs with the potential of identifying newer drugs in the future.

Title: Novel reagents and assays indicate a role for NADPH oxidase 2 in Parkinson disease

Authors: *J. T. GREENAMYRE, E. K. HOFFMAN, M. T. KEENEY, J. MCCOY, P. J. PAGANO, R. DI MAIO;
Neurol., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Mitochondrial defects and oxidative stress have been strongly implicated in the pathogenesis of Parkinson disease (PD). While it is generally assumed that the oxidative stress and damage seen in PD derive from mitochondria, there is growing evidence that reactive oxygen species (ROS) generated by NADPH oxidase 2 (NOX2) may be important. Indeed, mitochondrial dysfunction and NOX2 are intimately related. While there is some evidence that NOX2 inhibitors may protect dopaminergic neurons against degeneration, these studies have often been hampered by the lack of highly specific inhibitors. Additionally, it has been difficult to assess the activation state of NOX2 under experimental or pathological conditions with a cellular level of resolution. We now report testing of a novel and highly specific NOX2 inhibitor, Nox2ds-tat, and development of a new histological assay for NOX2 activation that is based on association of NOX2 and $p47^{phox}$, which is required for activation, and detected by proximity ligation.

To model certain aspects of PD in vivo and in vitro, we used the mitochondrial complex I toxin, rotenone. In SH-SY5Y cells exposed to sublethal rotenone, there was clear-cut activation of NOX2. Similarly, in rotenone treated rats, there was strong activation of NOX2 in nigrostriatal dopamine neurons. Importantly, the PL assay also detected NOX2 activation in dopamine neurons in brains of patients with PD. Thus, NOX2 activation occurs in vulnerable neurons in PD and models thereof.

In cell culture and in vivo, rotenone causes first (i) accumulation, then (ii) oligomerization, and later, (iii) fibrillization/aggregation of α-synuclein. Nox2ds-tat is a peptide that blocks association of NOX2 and $p47^{phox}$, thereby preventing NOX2 activation. Co-treatment of cultures with rotenone and Nox2ds-tat prevented the rotenone-induced accumulation, oligomerization and aggregation of α-synuclein.

Oligomeric α-synuclein binds to TOM70, a mitochondrial receptor that binds proteins containing an internal mitochondrial targeting signal. To facilitate import of these proteins, TOM70 also interacts with Hsp70 to prevent misfolding/aggregation of proteins to be imported. Rotenone

disrupts the normal TOM70:Hsp70 interaction and this is prevented by co-treatment with Nox2ds-tat, presumably because it reduces rotenone-induced oligomerization of α-synuclein. Together, these results indicate (i) that NOX2 activation occurs in PD, (ii) that NOX2 activity contributes to α-synuclein pathology, and (iii) that NOX2 activity contributes to mitochondrial impairment.

Title: Inhibition of LRRK2 prevents rotenone induced reduction of glucocerebrosidase activity.

Authors: *E. N. ROCHA, E. HOFFMAN, R. DI MAIO, P. J. BARRETT, J. T. GREENAMYRE;
Pittsburgh Inst. for Neurodegenerative Dis., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Mutations in *LRRK2* are the most common monogenic cause of Parkinson disease (PD) and mutations in *GBA1* are the most common risk factor for the disease. Whether and how these 2 genes and their protein products interact physiologically is unknown. LRRK2 is a kinase that has been associated with several pathways including autophagy, and mutations in LRRK2 are associated with enhanced kinase activity. *GBA1* encodes a lysosomal hydrolase, glucocerebrosidase (GCase), and mutations are associated with loss of function and increased α-synuclein accumulation. Further, we previously reported a ~50% loss of GCase activity in substantia nigra of young idiopathic PD brains. In an effort to model aspects of PD in vitro and in vivo, we have employed the mitochondrial complex I toxin, rotenone. Recent data has suggested that rotenone causes an autophagy deficit; however, the effect of rotenone on GCase activity has not been explored. Rotenone also increases α-synuclein and, as reported elsewhere at this meeting, it can activate LRRK2 in vitro and in vivo. We now report that in cultured SH-

SY5Y cells, sublethal rotenone inhibits GCase activity by about 50% without causing overt toxicity or cell loss. In rotenone-treated rats, we have found a similar ~50% loss of GCase activity in substantia nigra - as seen in the human disease. GCase activity was unchanged in striatum and hippocampus. Interestingly, in the SH-SY5Y cells, co-treatment with the selective LRRK2 kinase inhibitor, GNE-7915 (50-500 nM), prevented the rotenone-induced loss of GCase activity. Our data suggest that mitochondrial complex I defects can alter lysosomal function, potentially reducing degradation of α-synuclein. Additionally, LRRK2 activity contributes to the impairment of GCase activity that is caused by mitochondrial dysfunction.

Title: Glatiramir acetate (Copaxone) causes restoration of the nigrostriatal pathway in a progressive MPTP mouse model of Parkinson's disease.

Authors: *C. K. MESHUL[1,2], M. J. CHURCHILL[1];
[1]Neurocytology Lab/Bldg 101, Room 520, VA Med. Ctr., Portland, OR; [2]Behavioral Neurosci., OHSU, Portland, OR

Abstract: Patients with Parkinson's disease (PD) have been shown to have an increased inflammatory response as the disease progresses (Greer et al., 2008) and is associated with activation of the pro-inflammatory m1 subtypes of microglia. There are also m2 types of microglia that act as an anti-inflammatory. These m2 subtypes secrete growth and regenerative factors into the area of the injury (Olson and Grendelman, 2016). A shift from the pro-inflammatory microglia (m1) to the anti-inflammatory (m2) subtypes could be therapeutically relevant in PD by allowing the m2 subtypes to promote recovery of dopamine (DA) neurons and terminals. Yang et al. (2016) reported that after directly infusing IL-4 (an activator of m2 subtypes) into the area of an intracerebral hemorrhage, there was improvement in neurobehavioral tests. Glatiramir acetate (GA)(Copaxone), a current therapy for MS, is a known microglial activator that polarizes the m1 subtypes into m2. To test GA in a more clinically relevant neurorestoration model, we utilized a mouse model of PD by administration of MPTP

over a 4-wk time frame that results in a 50-70% loss of DA (Goldberg et al., 2011). GA treatment (1.5mg/kg or 3.5 mg/kg i.p) was initiated following (i.e., restoration) 4 weeks of MPTP administration. Grip test analysis revealed that the MPTP only group had a 50% increase in grip strength compared to the vehicle group (p=0.0001). This was attenuated in the MPTP+GA group, resulting in only a 12% increase in grip strength compared to the vehicle group (p=0.0004) **despite** the previous administration of MPTP. Optical density and protein analysis for tyrosine hydroxylase (TH) in both the striatum and substantia nigra (SN) revealed a 65% loss of TH in the MPTP only group compared to the vehicle group (p=0.0001). In comparison, there was **only** a 13% loss of TH in the MPTP+GA compared to the vehicle group despite 4 weeks of previous MPTP administration (p=0.0191). IBA1, a structural protein of microglia, was increased in the SN by 163% in the MPTP only group (p=0.0001). This increase was reversed in the MPTP+GA groups to the level of the vehicle group (p=0.46). This suggests that GA caused a decrease in either number or size of the microglia. Microglial markers typifying the two subtypes, nitric oxide synthase 2 (m1) and arginase 1 (m2) showed no changes, compared to either the vehicle or MPTP groups. Overall, our data suggests that GA caused a recovery of the TH within the remaining DA neurons of the SN, resulting in improved motor function and TH levels within the striatum. Interestingly, the microglia analysis suggests that GA results in neurorestoration through downregulation of microglia rather than polarizing the m1 subtypes into m2.

Title: N-acylethanolamine acid amidase (NAAA) as a therapeutic target for Parkinson’s disease

Authors: *S. PONTIS[1], N. REALINI[1], F. PALESE[1], A. ARMIROTTI[1], M. LANFRANCO[1], D. PIOMELLI[1,2];
[1]Inst. Italiano Di Tecnologia, Genova, Italy; [2]Departments of Anat. and Neurobiology, Pharmacol. and Biol. Chem., Univ. of California, Irvine, Irvine, CA

Abstract: Abnormal innate immune responses and, in particular, microglia activation are thought to contribute to the pathogenesis of Parkinson’s disease (PD) (Holmans et al., 2013; Tansey and Goldberg, 2010). The lysosomal cysteine hydrolase, N-acylethanolamine acid amidase (NAAA), regulates immune responses in peripheral tissues by deactivating the fatty acid

ethanolamides, a family of anti-inflammatory lipid amides produced by macrophages and other host defense cells (LoVerme et al., 2005; Solorzano et al., 2009). Expression of NAAA in the healthy mouse brain is virtually undetectable (Tsuboi et al., 2007), but our preliminary studies show that it can be rapidly and persistently induced by intra-striatal administration of the neurotoxin 6-hydroxydopamine (6-OHDA). Immunofluorescence (IF) experiments show that 6-OHDA injections cause, within 48 h, a transient increase in NAAA expression in dopaminergic neurons (tyrosine hydroxylase positive, TH+) of the substantia nigra pars compacta (SNc), followed by a profound and long-lasting (2-3 weeks) NAAA induction in Iba-1+ microglia of striatum and SNc. To investigate the significance of these changes, we used mice that either overexpress NAAA in cells of monocyte lineage (CD11b+), including microglia (NAAA-ki mice), or constitutively lack NAAA expression (NAAA-ko mice). NAAA-ki mutants were obtained by crossing CD11b-Cre mice with heterozygous NAAA conditional knock-in mice in which the NAAA coding sequence was inserted within the Rosa26 locus. The animals are viable, fertile and display cell-appropriate NAAA overexpression. Compared to wild-type controls, NAAA-ki mice treated with intrastriatal 6-OHDA show substantially higher: (i) behavioral response to the dopamine receptor agonist apomorphine; (ii) TH+ neuron toxicity in the SNc (15.96±0.54% vs 26.78±0.36%; n=4); and (iii) mortality (47.8±4.8% vs 25.0±3.0%; n =20). The NAAA-ko mice [Naaatm1a(KOMP)Wtsi] were generated at the Welcome Trust Sanger Institute and obtained from Jackson Labs. The mice express a frame-shifted catalytically inactive protein, and are viable and fertile. Compared to wild-type mice, NAAA-ko mutants display significantly lower (i) behavioral responses to apomorphine (Fig. 1); (ii) TH+ neuron toxicity in the SNc (51.54±2.9% vs 26.78±0.36%; n =4); and (iii) mortality 16.6±5.3% vs 25.0±3.0%; n = 20). Collectively, the results suggest that NAAA is critically involved in the neuronal and microglial response to 6-OHDA, and that small-molecule agents targeting this enzyme may interrupt the pathological process initiated by the neurotoxin.

Title: The neurorestorative potential of cortical disinhibition in a progressive mouse model of Parkinson's disease

Authors: *R. HOOD[1], C. K. MESHULK[1,2];
[1]Behavioral Neuroscience, Oregon Hlth. & Sci. U, Portland, OR; [2]Portland VA Med. Ctr., Portland, OR

Abstract: Parkinson's disease (PD) is a neurodegenerative disorder affecting 7-10 million people worldwide. Through a progressive loss of dopaminergic cells in the substantia nigra pars compacta (SNpc), signaling in the basal ganglia becomes dysfunctional, leading to declining motor and cognitive function. Targeting brain regions affected by PD may alleviate neurodegeneration that occurs in PD. Because motor cortex (MC) activation is altered and repetitive transcranial magnetic stimulation can temporarily attenuate symptoms in PD patients, we believe that the MC is a viable therapeutic target. We have shown that MC disinhibition through unilateral *Vgat* (the gene encoding the vesicular GABA transporter VGAT) knockout in the motor cortex of Vgatflox/flox mice is neuroprotective. Mice were stereotaxically injected with AAV-Cre-GFP unilaterally targeting the MC and then subjected to 4 weeks of an increasing dose of MPTP, 5 d/wk, injected i.p. at doses of 8, 16, 24, and 32 mg/kg/d. Since VGAT is required for GABAergic function, we believe targeting GABAergic interneurons with focal AAV-Cre-GFP prevents inhibitory GABAergic signaling in the MC. Control animals exhibit a 79% loss of tyrosine hydroxylase (TH) in the striatum after MPTP lesioning, and this loss was completely prevented by cortical disinhibition following AAV-Cre-GFP injection. Similarly, control animals showed a 59% loss of TH-expressing cells in the SNpc after MPTP lesioning and this loss was completely prevented by cortical disinhibition. However, this paradigm uses a neuroprotective design in which the therapy is administered before neurotoxic insult. While the results are promising, this study design is not clinically relevant. Therefore, we investigated the neurorestorative potential of cortical disinhibition in which mice were subjected to MPTP lesioning first and then immediately injected with either AAV-Cre-GFP or AAV-GFP unilaterally in the MC. Based on previous therapies tested with our model that were beneficial in both protective and restorative study designs, we hypothesized that cortical disinhibition will restore physiological or motor dysfunction observed after MPTP lesioning. Observing restoration in this study would suggest that cortical disinhibition could be an effective novel therapy for PD.

Title: Neuroprotective effects of α7 nicotinic acetylcholine receptor through the Wnt/β-catenin signaling pathway in both *In vivo* and *In vitro* models of Parkinson's disease.

Authors: *H. JUN[1], Y. FAN[2];
[1]The First Affiliated Hosp. of Nanjing Med. Univ., Jiangsu, China; [2]Dept. of Pharmacol. of Nanjing Med. Univ., Nanjing, China

Abstract: A growing body of evidence indicates that α7 nicotinic acetylcholine receptors (α7-nAChRs) play an important role in chronic inflammatory and neurodegenerative disease. However, the molecular mechanisms are still unknown. The objectives of the present study were to explore the potential of the α7-nAChRs activation for the treatment of Parkinson's disease (PD) and to determine whether its neuroprotective effects are exerted through the Wnt/β-catenin signaling pathway by using in vivo and in vitro models of PD. In the *in vivo* study, the α7 mutant mice (KO) aggravated the behavioral deficits of "Pole test", and dopaminergic cell loss that were induced by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) in a dose-dependent manner in an in vivo model of PD. In the *in vitro* study, cell damage induced by 1-methyl-4-phenylpyridinium (MPP+) was ameliorated by nicotine pretreatment. Nicotine induced protective effects on the protein and mRNA expression levels of markers of the Wnt/β-catenin signaling pathway in both the *in vivo* and the *in vitro* studies, and these neuroprotective effects were abolished by the α7 KO mice in the *in vivo* study or the α7-nAChR-selective antagonist in the *in vitro* study. Our results provide evidence that activation of α7-nAChRs has neuroprotective effects in both *in vivo* and *in vitro* PD models, and these effects act through the Wnt/β-catenin signaling pathway. Taken together, these results indicate that α7-nAChR agonist may exert therapeutic effects on PD via the Wnt/β-catenin signaling pathway and may therefore provide a novel approach for the treatment of PD.

Title: Neuroprotective effect of dimethyl fumarate in mptp-mouse model of parkinson's disease

Authors: *E. ESPOSITO, F. BIUNDO, G. CASILI, M. CAMPOLO, R. CRUPI, M. CORDARO, S. CUZZOCREA;
Univ. of Messina, Messina, Italy

Abstract: Oxidative stress is central in Parkinson's disease (PD) and nuclear transcription factor related to NF-E2 (Nrf-2) is involved in neuroprotection against PD. The aim of the present study was to investigate the neurotherapeutic action, Nrf-2 dependent, of DMF in a mouse model of PD. Mice received four injections of the dopaminergic neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). Starting 24 h after the first administration of MPTP, animals were treated with DMF (10, 30 and 100 mg/kg, by oral gavage) daily for 7 days and, on the 8th day mice were subjected to behavioural test. DMF treatment significantly reduced neuronal degeneration of dopaminergic tract and behavioral impairments induced by MPTP administration. Moreover, treatment with DMF prevented dopamine depletion increasing tyrosine hydroxylase (TH) and dopamine transporter (DAT) and also reduced α-synuclein-positive neurons. Furthermore, DMF treatment up-regulated Nrf-2 pathway, increasing $NeuN^{+}$/$Nrf\text{-}2^{+}$ cells in the striatum and inducing activation of manganese *superoxide dismutase* (Mn-SOD) and heme-oxygenase-1 (HO-1). Also, DMF reduced ciclo oxygenase 2 (COX-2), lowered nitrotyrosine (NT) and neuronal nitrite oxide synthase (nNOS) expression, restored *nerve growth factor* (*NGF*) levels and preserved by microtubule-associated protein 2 (MAP-2) alterations. These results support the thesis that DMF may constitute a promising therapeutic target for the treatment of PD.

Title: Recovery of motor functions in a Parkinson's disease rat model after releasing dopamine from titanium dioxide matrix implants

Authors: *M. GÓMEZ-CHAVARÍN[1,2], P. PADILLA[1], J. RAMIREZ-SANTOS[1], G. PRADO-PRONE[3], J. GARCÍA-MACEDO[3], G. GUTIERREZ-OSPINA[1];
[1]UNAM-Biomedical Res. Institutute, Mexico D. F., Mexico; [2]UNAM-Medicine Fac., Mexico, Mexico; [3]Solid State Physics, UNAM-Physics Inst., Mexico, Mexico

Abstract: Motor symptoms of Parkinson's disease (PD) are in part due to the depletion of dopamine (DA) in the caudate nucleus (CN). Insufficient availability of DA follows the loss of dopaminergic neurons in the substantia nigra (SN). Treatment with L-DOPA, a precursor of dopamine, partly restores motor function in Parkinson's disease patients. This treatment, however, requires the remaining nigral dopaminergic neurons to be able to synthesize dopamine. Since these neurons die progressively as the disease advances, L-DOPA becomes increasingly ineffective in attenuating motor symptoms in patients. It is then needed to develop a way to provide DA to the CN. Unfortunately, DA is oxidized rapidly after being released, a process that renders it biologically inactive if provided chronically with no protection. Hence, in this work we tested a semi-solid matrix made of titanium dioxide (TiO_2) as a mean to release chronically DA into the CN while avoiding its oxidation. We then implanted TiO_2 matrices with or with out DA in the CN of adult male Wistar rats exposed to rotenone (1mg/kg during 21 days), an herbicide that induces PD-like motor symptoms in rodents. Recovery of motor functions was evidenced through motor coordination tests. Histological surveys were also carried out. Before implantation, DA loaded matrices were subjected to infrared spectroscopy, high resolution transmission electron microscopy, X-ray diffraction and HPLC analyses to establish the molecular structure of the lattice and to evaluate its ability to carry, protect and release DA. Once corroborated their physicochemical properties, the matrix was stereotaxically implanted in the dorsal CN and the rats were evaluated one and two months later. Our results show that ROT-exposed display significant deficits of motor coordination as compared to control rats. Such deficits were reversed in most ROT-exposed rats implanted with matrices releasing DA, but not in those implanted with unloaded matrices. The histological procedures revealed implants to be correctly allocated and showed increments of tyrosine hydroxylase immune-reactivity in the *substantia nigra* and CN ipsilateral to the implanted matrix. Tyrosine hydroxylase immune-positive cells were also observed in the subventricular zone. Together our results support that TiO_2 manufactured matrices constitutes an effective device to release chronically biologically active DA into DA-depleted CN.

Title: Long-term transgene expression in rat brain after intranasal administration of hGDNF DNA nanoparticles and enhancement by focused ultrasound (FUS)

Authors: *A. E.-E. ALY[1], T. SUN[2], Y. ZHANG[2], O. SESENOGLU-LAIRD[3], L. PADEGIMAS[3], M. J. COOPER[3], N. J. MCDANNOLD[2], B. L. WASZCZAK[1];
[1]Pharmaceut. Sci., Northeastern Univ., Boston, MA; [2]Radiology, Harvard Med. Sch. and Brigham & Women's Hosp., Boston, MA; [3]Copernicus Therapeut., Cleveland, OH

Abstract: The therapeutic potential of glial cell-line derived neurotrophic factor (GDNF) for treating Parkinson's disease (PD) has been limited thus far by its inability to cross the blood-brain barrier (BBB). We have previously shown that intranasal administration of PEGylated lysine 30-mer (CK30PEG10K) DNA nanoparticles (NPs) encoding hGDNF, developed by Copernicus Therapeutics, Inc., can transfect brain cells in vivo, induce transgene expression, and provide neuroprotection of substantia nigra (SN) dopamine neurons in the rat 6-hydroxydopamine model of PD. We have also shown using double-label immunohistochemistry that transgene expression in the rat brain occurs primarily in cells lining the vasculature, most likely pericytes.
The first goal of our current study was to assess the duration of eGFP expression after intranasal administration of DNA NPs which encode an eGFP-GDNF fusion protein. Rats were sacrificed 1 week, 3 months, or 6 months after intranasal administration. Analysis of eGFP expression at the 3 time points revealed that transgene expression was highest at one week, and persisted at ~30% of maximal levels at both the 3 and 6 month time points.
Although intranasal administration allows large biomolecules to bypass the BBB, it is a low efficiency route of administration and results in widespread distribution with no means of targeting specific brain regions. Focused ultrasound (FUS) combined with a circulating microbubble agent has been shown to enhance delivery of macromolecules to the brain by transiently disrupting the BBB. Our second goal was to evaluate whether FUS can be combined with intranasal administration of our DNA NPs, as well as the naked plasmids, to yield greater overall delivery, improved tissue penetration, and enrichment of transgene expression in the desired location(s) in brain. Results from a pilot study in 3 rats in which the naked plasmid was administered intranasally in conjunction with FUS and microbubbles provided evidence that the amount of transgene expression was increased on the sonicated versus the unsonicated side of the

brain, and overall whole brain eGFP weighted averages were significantly increased in the sonicated rats. Ongoing studies will examine the effect of FUS on transgene expression in the sonicated regions, and will assess tissue penetration and cell types transfected after intranasal administration of our DNA NPs.

Abstract: We evaluated a canine model with a homozygous splice donor mutation in the *SERAC1* gene as a potential animal model for MEGDEL syndrome and juvenile Parkinson disease. Metabolic profiling, lipidomics, phenotyping and imaging showed almost full overlap with those of patients with MEGDEL syndrome, including significant mitochondrial dysfunction of various complexes of the electron transport chain in a brain area specific manner as well as elevated phosphatidylglycerol-34:1 to phosphatidylglycerol-36:1 ratio. The neurologic phenotype showed early ataxia and later hypokinesia and postural instability. Brain

investigations detected cerebellar atrophy and basal ganglion involvement similar to juvenile Parkinson disease.
Our studies show novel and significant metabolic consequences in the *SERAC1* deficient brain, including abnormal cardiolipin synthesis and OXPHOS complex deficiencies. *SERAC1* is a complex lipid disorder and a new member of this evolving novel group of inborn errors of metabolism. As with several other complex lipid synthesis disorders, it has a presentation of juvenile Parkinson disease. The canine *SERAC1* mutant can be used as an animal model in future therapeutic trials in phospholipid related ataxia/dystonia.

Title: Therapeutic repurposing of raloxifene as an immunomodulatory drug for the treatment of gut inflammation in a mouse model of Parkinson's disease

Authors: *A.-A. POIRIER[1,2], M. CÔTÉ[1,3], M. BOURQUE[1,2], M. MORISSETTE[1], T. DI PAOLO[1,2], D. SOULET[1,3];
[1]Ctr. De Recherche Du CHU De Québec (CHUL), Quebec, QC, Canada; [2]Faculté de Pharmacie, [3]Faculté de médecine, psychiatrie et neuroscience, Univ. Laval, Québec, QC, Canada

Abstract: Motor symptoms in Parkinson's disease (PD) are often preceded by non-motor symptoms related to dysfunctions of the autonomic nervous system such as constipation, defecatory problems and delayed gastric emptying. These gastrointestinal disorders are associated with the alteration of dopaminergic (DA) neurons in the myenteric plexus (MP) of the gut. Studies in our laboratory have already demonstrated the immunomodulatory effect of female sex hormones to treat neurodegeneration in the 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) mouse model of enteric nervous system degeneration in PD and the implication of the G protein-coupled estrogen receptor 1 (GPER1). The objective of this project was to evaluate the

neuroprotective and immunomodulatory role of raloxifene, a selective estrogen receptor modulator already used for osteoporosis treatment. Adult C57BL/6 male mice received, daily for ten days, 2 injections of raloxifene (62.5 g) and/or G15 (10 or 50 g), a specific antagonist of GPER1. On day five, 4 injections of saline or MPTP (4.75 mg/kg) were administered. On day ten, mice were killed, the ileum was fixed and microdissected to isolate the MP. Cuprolinic blue staining and immunohistochemistry with antibodies against tyrosine hydroxylase (TH) and ionized calcium-binding adapter molecule 1 (Iba-1) were performed for stereological counting of total neurons, DA neurons (TH^+) and macrophages ($Iba\text{-}1^+$). We measured a loss of about 85% of TH^+ neurons in MPTP mice while control levels were maintained following raloxifene treatment. No difference in total neurons counts between groups was observed, suggesting that neuronal loss was specific to TH^+ neurons. Moreover, we observed an increase of approximately 55% in the number of macrophages in MPTP mice, while control levels were maintained with raloxifene treatment, demonstrating a significant anti-inflammatory effect of the drug in MPTP animals. When administered along with the antagonist G15, raloxifene did not lower the number of macrophages, indicating the important implication of GPER1. In addition, neurotoxin-induced proinflammatory polarization of human monocytic THP-1 cells, nuclear factor kappa B response and nitric oxide and proinflammatory cytokines production were also prevented by raloxifene *in vitro*. Overall, the present results demonstrate that raloxifene treatment prevent damages to DA neurons in the MP in a MPTP mouse model of Parkinson's disease, mainly through anti-inflammatory effects.

Abstract: The histopathological hallmarks of Parkinson's disease (PD) include dopamine cell loss in the midbrain substantia nigra pars compacta and the formation of alpha-synuclein-rich intraneuronal inclusions, called Lewy bodies, in surviving neurons. Prior studies support a role for alpha-synuclein (α-Syn) in the pathogenesis of PD. Thus, approaches aimed at reducing the expression of α-Syn in the substantia nigra using small interfering RNAs (siRNAs) may be therapeutic. Whether prolonged suppression of wildtype α-Syn expression can be well tolerated in the adult brain is unclear. Here, we locally delivered varying concentrations of an siRNA construct directed against α-Syn into the subtantia nigra of 18 adult female rhesus macaques (n= 6 per concentration) at an infusion rate of 0.1 µL/min for 28 days using a pump and catheter system. Tolerability of prolonged α-Syn inhibition was assessed by clinical observations as well as by neurochemical and histopathological examinations of the striatum and midbrain regions. Histopathological examination of preserved tissues was performed by a board-certified veterinary pathologist with specific expertise evaluating the nervous system. Histopathological evaluations indicated that the catheter tip was placed in or near the subtantia nigra pars compacta region in all animals. Molecular analyses of mRNA levels from midbrain tissue punches indicated significant silencing of α-Syn expression ranging from 88.3±3.2% at a concentration of 6 mg/mL to 96.6±0.9% at a concentration of 18 mg/mL versus controls. There were no indications of toxicity as noted in clinical observations and body weight values. There were no test article-related changes in striatal dopamine content and no microscopic changes in the cerebrum/neocortex, ventricular system or limbic system/hippocampus. Microscopic changes in the midbrain were not related to the test article, but attributed to catheter placement including slight/minimal bleeding, astrocytic and microglial cell reaction, extracellular fluid and local tissue loss. There was no evidence of necrotic neurons in any of the midbrain sections evaluated. The microscopic changes noted did not result in clinical signs. Overall, our data support that targeted, intranigral delivery of siRNAs designed to suppress α-Syn expression should be further evaluated as a potential therapy for PD.

Title: The Role of PAN nuclease in Parkinson's disease

Authors: *H. PARK[1], T.-I. KAM[1], T. M. DAWSON[2], V. L. DAWSON[2];
[2]Departments of Neurology, Neurosci. and Pharmacol. & Mol. Sci., [1]Inst. For Cell Engineering, Johns Hopkins Univ., Baltimore, MD

Abstract: Parkinson's disease (PD) is a common neurodegenerative disorder characterized by the loss of dopamine (DA) neurons in the substantia nigra pars compacta and the accumulation and aggregation α-synuclein (α-syn). Misfolded fibrillar forms of α-syn are thought to spread via cell-to-cell communication contributing to the progression and neurodegeneration in PD. However, the underlying molecular mechanisms by which α-syn causes cell death and neurodegeneration in PD is not known. Here, we show that the PAN nuclease mediates α-syn-induced degeneration in A53T transgenic mice. Conditional expression of the familial associated A53T α-syn mutant in DA neurons of transgenic mice leads to loss of DA neurons and behavioral deficits that is significantly reduced in the absence of the PAN nuclease. Further, we developed an endonuclease assay and screened a novel hybrid macrocyclic rapafucin library (~11,248 compoinds) to find PAN nuclease inhibitors. Novel PAN nuclease antagonists can inhibit DNA cleavage and prevent α-syn induced degeneration. Thus, targeting PAN nuclease activity may provide an important therapeutic opportunity in Parkinson's disease.

Abstract: Mutations in the gene SNCA that encodes the protein alpha-synuclein as well as postmortem pathological studies strongly implicate a general role for alpha-synuclein in Parkinson's disease (PD) pathogenesis. Thus, SNCA and alpha-synuclein are attractive targets for developing novel therapeutic approaches for PD patients. A field-wide challenge in PD research however, is a general lack of availability for high-quality, reproducible, and readily accessible preclinical research tools. To address these challenges, The Michael J. Fox Foundation for Parkinson's Research (MJFF) has developed a growing resource of preclinical tools for the PD research and drug development communities that endeavors to provide researchers with easy access to rigorously validated, research-enabling preclinical tools for molecular biology studies. Here we summarize our characterization and validation data for our anti-alpha-synuclein monoclonal antibody which was recently launched for commercial use. This monoclonal antibody is conformation specific for aggregate alpha-synuclein and binds with very high affinity and exquisite specificity for aggregate over monomeric versions of the protein. Both linear and cyclic epitope mapping data for this antibody are also provided. In addition, we describe our recently developed and commercially launched alpha-synuclein protein library, which contains multiple versions of recombinant alpha-synuclein proteins and a pS129 phospho-mimetic peptide. Moreover, we introduce new alpha-synuclein molecular biology reagents that are currently in development within our preclinical tools pipeline, including an alpha-synuclein toxicity and aggregation assay. Ultimately, these MJFF-sponsored alpha-synuclein research tools aim to address field-wide challenges in the preclinical tools and reagents space and overall accelerate PD research.

Title: Aldh1a1 is expressed by two dopamine neuron subtypes with distinct molecular and neuroanatomical properties

Authors: *J.-F. POULIN[1], C. M. ESTEP[2], Q. CUI[2], B. HELM[3], C. S. CHAN[2], D. J. SURMEIER[2], R. AWATRAMANI[3];
[1]Neurosciences, Northwestern Univ. - Chicago, Chicago, IL; [2]Physiol., [3]Neurol., Northwestern Univ., Chicago, IL

Abstract: We recently assessed the molecular diversity of midbrain dopamine neurons, using a single-cell high-throughput gene expression platform based on microfluidic qRT-PCR arrays. This approach revealed multiple molecularly distinct dopamine neuron subtypes, two of which displayed high expression of *Aldh1a1*, a gene belonging to the aldehyde dehydrogenase family. These two dopamine neuron subtypes can be differentiated by the expression of the transcription factors *Sox6* and *Otx2*. To further characterize these two subtypes, we generated a mouse in which the *Aldh1a1* genomic locus was modified to drive the expression of tamoxifen-inducible recombinase CreER^{T2}. We report that one of these subtype is located in the ventral tier of the substantia nigra (SNc) and sends strong projections to the lateral region of the dorsal striatum. The neurons of this subtype were previously found to be more vulnerable in the MPTP model of Parkinson's disease. The other *Aldh1a1*+ subtype is located in the ventral tegmental area (VTA) and projects principally to the medial part of the nucleus accumbens. Electrophysiological analysis that *Aldh1a1*-expressing dopamine neurons in the SNc displayed larger SK and HCN

currents compared to those in the VTA. We are currently exploring the functions of these two dopamine neuron subtypes using the Aldh1a1::CreER^{T2} mouse.

Title: Base excision repair variants and pesticide exposure increase Parkinson's disease risk

Authors: *L. H. SANDERS[1], K. C. PAUL[2], E. H. HOWLETT[4], X. HU[4], J. M. BRONSTEIN[3], B. RITZ[2], J. GREENAMYRE[4];
[1]Pittsburgh Inst. Neurodegenerative Dis., Univ. Pittsburgh, Pittsburgh, PA; [2]Epidemiology, [3]Neurol., UCLA, Los Angeles, CA; [4]Neurol., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: We recently reported selective mitochondrial DNA (mtDNA) damage in the form of abasic sites in the vulnerable nigral neurons in Parkinson's disease (PD). The persistence of abasic sites suggests an ineffective base excision repair (BER) response in PD. In addition, we recently showed that pesticide exposure, which has been linked to PD risk, can cause mtDNA damage. The objective of this study was to investigate the joint impact of variations in genes involved in the BER system and pesticide exposure. To determine whether either *APEX1* rs1130409 or *OGG1* rs1052133 polymorphisms was independently associated with PD, 619 PD patients early in disease and 854 population controls were examined. PD risk was not influenced by either genotype alone. We next investigated whether there were interactions for either BER polymorphism and pesticides. We detected statistically significant (p=0.05) or near significant (p=0.07) interactions for both *APEX1* rs1130409 and *OGG1* rs1052133 and ambient oxidative

stress exposure. At both loci, for pesticide exposed risk allele carriers we estimated more than multiplicative risk increase. Specifically, for *OGG1* rs1052133, the risk was increased by almost 80% in exposed variant carriers (OR=1.79, 95% CI=1.22-2.64). Similarly, for *APEX1* rs1130409, in exposed T allele carriers experienced a 67% increase in risk (OR=1.67, 95% CI=1.13-2.47). The strongest interactions we identified were for the combined BER genetic risk score and pesticide exposures; we detected more than a multiplicative risk with both oxidative stress inducing pesticide exposure (p=0.01) and mitochondrial inhibiting pesticide exposure (p=0.07). The highest risk was estimated for the joint effect of pesticide exposure and the two risk genotypes (mitochondrial inhibitor exposure: OR=2.32, 95% CI=1.44-3.75; oxidative stressor exposure: OR=2.21, 95% CI=1.45-3.38). One of the pesticides analyzed in our study, paraquat, induces oxidative stress by redox cycling. We found mtDNA damage was increased and mitochondrial function impaired following acute paraquat exposure in *in vitro* neuronal cultures. This is the first study to discover variants in BER enzymes interact with pesticide exposure to increase the risk of PD.

Title: Multifunctional neuroprotection by astrocyte-specific DJ-1 expression in the rotenone model of Parkinson’s disease

Authors: *B. R. DE MIRANDA, E. A. BURTON, J. T. GREENAMYRE;
Neurol., Univ. of Pittsburgh, Pittsburgh, PA

Abstract: The Parkinson’s disease (PD) protein DJ-1 accumulates in astrocytes of the substantia nigra (SN) and striatum (ST) of human postmortem tissue from PD patients, indicating a possible compensatory function for this redox sensitive protein in astrocytes. In addition, DJ-1 may be directly involved in the detoxification of alpha-synuclein, the major component of Lewy bodies. DJ-1 has also been reported in humans to act as a transcriptional co-activator of tyrosine

hydroxylase (TH), the enzyme responsible for dopamine production. Further, DJ-1 was reported to upregulate the transcription of the orphan nuclear receptor Nurr1, a protein involved in both the production of TH in developing dopamine neurons, as well as inflammatory gene suppression in mature astrocytes. In the current study, adult male Lewis rats were injected with MuLV-hDJ-1 (or MuLV-GFP control) in the ST and SN, followed by daily rotenone injection (2.8 mg/kg, IP) until motor endpoint was reached. Overexpression of hDJ-1 was associated with profound protection of SN cell bodies ($P<0.001$) and their terminals in ST ($p<0.0001$). To investigate potential mechanisms, histological analyses revealed that animals receiving the MuLV-GFP (control) transgene expressed significantly increased levels of total alpha-synuclein as well as phosphorylated alpha-synuclein (S129; $p<0.01$) within the dopaminergic neurons of the SN following rotenone treatment, a response that was markedly reduced in animals treated with the MuLV-hDJ-1 vector. In addition, the mitochondrial complex I protein NDUFS3 was significantly preserved in dopamine neurons of animals expressing the hDJ-1 transgene in astrocytes, compared to their MuLV-GFP counterparts ($p<0.05$). Protein levels of TH were increased at baseline in the ST of MuLV-hDJ-1 animals ($p<0.01$) and RNA Scope revealed this was a transcriptional effect. Interestingly, Nurr1 expression did not appear to be increased at baseline, but was significantly increased in the dopamine neurons of MuLV-hDJ-1 animals following rotenone treatment, indicating that oxidative stress likely plays a role in the astrocyte-specific modulation of DJ-1 and its downstream functions. In summary, our results indicate that astrocytic overexpression of hDJ-1 is protective in an in vivo model of PD and multiple mechanisms may contribute to this effect.

Title: A longitudinal study of PINK1 and PARK7 KO rats

Authors: *N. W. MILGRAM[1,2], J. A. CASKANETTE[3], A. VAN NIEKERK[3], A. PATRICK[3], L. B. SILENIEKS[4], W. LAU[4], S. THEVARKUNNEL[4], J. A. ARAUJO[4], G. A. HIGGINS[4,2]; [1]Cancog Technologies, Toronto, ON, Canada; [2]U. Toronto, Toronto, ON, Canada; [3]Vivocore, Toronto, ON, Canada; [4]Intervivo Solutions Inc, Toronto, ON, Canada

Abstract: Epidemiological evidence suggests that exposure to environmental toxicants, such as rotenone are a risk factor for Parkinsons Disease (PD). Rotenone is an industrial pesticide that

induces toxicity by affecting complex I mitochondrial function and consequent oxidative damage. Various PD associated genes have also been identified, including Park7 (DJ-1) and Pink1, both of which have a role in mitochondrial homeostasis. Accordingly, both Park7 KO and Pink1 KO rats have been created using Zinc Finger Nuclease (ZFN) technology. A recent report (Dave et al (2014) Neurobiol. Dis. 70: 190-203) described motor changes emerging at 6-8 months age, notably in the Pink1 KO, and evidence for loss of DAergic neurons within the substantia nigra of both KO lines at 8 months. The purpose of the present study was to examine the motor behavioural phenotype of both the Pink1 and Park7 KO lines over a longer timespan (4-20 months age), and to examine the interaction of low dose rotenone administered chronically (3 x 0.5 mg/kg IP/week) on this phenotype. A total of 24 male Park7 KO and 24 Pink1 KO rats entered the study, with 24 of their respective wild type controls, i.e 96 rats in total. Twelve rats from each group received a saline injection 3x weekly, while the other 12 rats received a rotenone injection 3x weekly. Each week from W10 to W88, rats were scored on a simple 5 point scale based on hindlimb and general motor function (0=normal, 4=hindlimb paralysis). Bimonthly neurological assessments were also made, including measures of locomotor activity, beam walking, postural instability. At 20 months (W88) measures of cognitive function (novel object recognition task) and motor response to amphetamine challenge were also taken. The Park7 KO rats developed a modest neurological phenotype over the study duration. At W10 all scores were 0, and by W88, the Park7 KO group was significantly higher than wild type controls with a modest interaction with rotenone treatment (WT+veh: 0$\pm$0; WT+ROT: 0$\pm$0; Park7+VEH: 1.5$\pm$0.3; Park7+ROT: 2.5$\pm$0.4). The Pink1 KO line showed a distinct profile. At W26-32 the Pink1 KO rats had developed a robust neurological phenotype characterized by hindlimb weakness and dragging (e.g. W28 Pink1+VEH: 2.8$\pm$0.2), however by W52 these scores had declined to near WT levels (W52 Pink1+VEH: 0.9$\pm$0.2) suggesting a return of normal hindlimb function. This recovery was also confirmed by other indices of motor function. By W88 neurological scores had increased slightly but were still lower than W26-32. These studies thus characterize the motor phenotype of both KO lines over an extended lifespan and may suggest a subtle interaction between Park7 gene KO and chronic low dose rotenone exposure.

Title: Rab8A effects on alpha-synuclein toxicity in a rat model of Parkinsonism

Authors: *N. R. MCFARLAND[1], H.-J. PARK[2], D. RYU[2], L. POWELL[2], R. FOELS[2], M. PARMAR[2];
[1]Neurol., [2]Univ. of Florida, Gainesville, FL

Abstract: A major pathological hallmark of Parkinson disease is the presence of Lewy bodies that are enriched with the protein, alpha-synuclein (αS). Abnormal accumulation and deposition of αS are associated with ER stress, intracellular vesicle trafficking deficits, and cytotoxicity. Rab GTPases play critical roles in intracellular protein and vesicle trafficking, and expression of specific Rabs has been shown to ameliorate trafficking deficits and toxicity caused by αS overexpression. These findings suggest not only that abnormal accumulation of αS may interfere with normal Rab protein functions, but that RabGTPases also may play important role in αS homeostasis and reduce formation of toxic oligomers or aggregate formation. We and others have shown that Rab8A reduces αSyn and associated oligomer and aggregate formation in cellular models. In this study we aimed to test the impact of viral-mediated Rab8A expression on αSyn pathology *in vivo* in an adult rat model of Parkinsonism. We hypothesized that targeted viral expression of Rab8A in the substantia nigra would reduce formation of "toxic" αS oligomeric species, aggregates, and nigrostriatal dopamine toxicity. For this study adult Sprague dawley rats were unilaterally injected stereotaxically in the substantia nigra (SN) with recombinant adeno-associated virus (rAAV) serotype 2/8, expressing human αS (AAV-CBA-Syn-WPRE construct) or empty vector plus or minus N-terminal Flag-tagged Rab8A in 2 µL volume. All virus were individually tested at several titers for effects and nigrostriatal toxicity, and the concentration for AAV-Rab8A specifically chosen due to lack of independent toxicity in preliminary tests. At 8 weeks post injection, rats were sacrificed and brains extracted for analyses. The results demonstrate robust co-expression αS and Rab8A in animals that received combined rAAV injection. Viral expression of Rab8A alone (with empty vector) resulted in greater than expected dopamine cell loss (38.3%) in the SN as measured by tyrosine hydroxylase (TH) immunostaining. As expected αS expression caused significant TH cell loss at 8 weeks (65.4%), but when co-expressed with Rab8A there was no significant rescue (58.9%) of αS-induced TH cell loss in the SN. Similarly, there was no difference in relative TH expression in striatal tissues from rats injected with rAAV expressing Rab8A compared to those with empty vector. Together, these preliminary findings indicate that viral expression Rab8A is not sufficient to protect against αS toxicity in the rat nigrostriatal system. However, further studies are needed to assess adequate expression and effects on αS levels, aggregate formation, and toxicity.

Title: Increase of tau protein levels in sporadic and experimental parkinson's disease

Authors: *Y. CHU[1], Y. HE[2], J. H. KORDOWER[2];
[2]Neurolog. Sci., [1]Rush Univ. Med. Ctr., Chicago, IL

Abstract: Alpha-synuclein and tau are abundant brain proteins with distinct biological functions and intraneuronal distribution. Alpha-synuclein is mainly localized in axon terminals where it may regulate synaptic functions whereas tau is a microtubule binding protein that stabilizes and promotes microtubule polymerization. However, alpha-synuclein and tau are both partially unfolded proteins that can form toxic oligomers and abnormal intracellular aggregates under pathological conditions. Alpha-synuclein positive inclusions are also described in tauopathies and *vice versa*, suggesting a co-existence or crosstalk between these proteinopathies. The purpose of our study was to examine whether abnormal alpha-synuclein can induce tau accumulation in Parkinson's disease (PD). Twelve human brains from PD (n=6) and age-matched controls (n=6) as well as twelve rat brains receiving AAV-alpha-synuclein (n=6) or empty vector (n=6) were analyzed using immunohistochemistry. The colocalization of alpha-synuclein and tau accumulation was examined with immunofluorescent double labeling. The levels of tau were determined using densitometry. Colocalization analyses revealed that accumulated tau was observed in both nigral neurons with or without alpha-synuclein inclusions in PD. Compared to age-matched controls, a marked increase in perikarya tau immunoreactivities was observed in substantia nigra of PD. Increase in tau levels were recapitulated in a rat model of PD based on viral over-expression of human wild-type α-synuclein, suggesting that α-synuclein overexpression appear to promote tau accumulation in perikarya of nigral neurons. Our preliminary data demonstrate that interactions between tau and α-synuclein may form a deleterious feed-forward loop essential for the development and spreading of neurodegeneration.

Title: The effect of N-methylsasolinol on α-synuclein transgenic PD model

Authors: Z. CHEN, *H. MA, F. SUN, Y. DENG;
Sch. of Life Science, Beijing Inst. of Technol., BEIJING, China

Abstract: Parkinson’s disease(PD) is the second most common neurodegenerative disorder. The number of PD patients is expected to reach 10 million in the next 20 years worldwide,which will pose a huge burden on society.Loss of dopaminergic neuron in substantia nigra pars compacta (SNpc) and protein aggregation named lewy Bodies(LBs) are two important hallmarks of PD.A growing body of evidences suggested that CAIQ can cause the death of dopaminergic neurons including N-methylsasolinol(NMSal),which has been considered as one kind of endogenous neurotoxins to induce Parkinson's disease(PD).Aggregated α-synuclein(α-syn) is a major component of lewy bodies and the pathological changes of α-syn are considered to implicate in PD.In our project,we investigated whether CAIQ can enhance α-syn aggregation,lead to dopaminergic neurodegeneration and try to clarify the exact molecular mechanism of PD.We established α-syn transgenic rat model using adult male wistar rats through injecting α-syn overexpression recombinant adeno-associated viral (rAAV) by cerebral stereotaxic technique to the right SNpc of rats.After 12 weeks, the time node behavior test was performed and the rats showed apomorphine induced rotation to the left side which is a characteristic behavior to loss of dopaminergic neurons. The effect of NMSal on dopamine and its metabolites, oxidative stress,mitochondrial damage and α-syn aggregation will be evaluated. 100nmol NMSal was injected to the same site with rAAV injection and the behavior test showed that the NMSal accelerated apomorphine induced rotation in rAAV-α-synuclein groups after 4 weeks post injection.The levels of malondialdehyde(MDA),reactive oxygen species(ROS),endogenous neurotoxins(Salsolinol and NMSal)and loss of dopaminergic neurons were all elevated in the α-syn transgenic rats after NMSal induction. In addition,we also observed that NMSal enhanced the aggregation of α-syn.These results indicated that NMSal can enhance the dopaminergic neurotoxin induced by α-syn overexpression. Moreover,we further explored the effect mechanism of NMSal on α-syn aggregation by detecting the degradation pathways of α-syn.The results showed that NMSal can inhibit the expression of Beclin-1, Atg5 and Atg3 which are associated with autophagy-lysosomal pathway(ALP).So NMSal may increase α-syn aggregation

by inhibiting the degradation of α-syn through autophagy-lysosomal pathway(ALP). Our project provided a evidence that the interaction between NMSal and α-syn might be involved in PD pathogenesis.This study will give a new insight into the development and treatment of PD.

Biol., Univ. of Cincinnati, Cincinnati, OH; [4]Univ. of California San Diego, La Jolla, CA; [5]Human Genet., Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH; [6]Neurodegenerative Dis. Inst., Univ. of Bordeaux, Bordeaux, France

Abstract: Loss of function mutations in the gene *ATP13A2* are associated with the neurodegenerative diseases Kufor-Rakeb Syndrome and Neuronal Ceroid Lipofuscinosis. The function of ATP13A2 is unclear but in vitro studies suggest that it is involved in the lysosomal degradation of proteins and in the homeostasis of heavy metals including zinc and manganese. We previously showed that *Atp13a2-deficient* (13a2) mice develop age-dependent sensorimotor deficits, enhanced lipofuscinosis, and accumulation of insoluble alpha-synuclein (aSyn) in the brain. More recently, we also showed they are more sensitive to the toxic effects of manganese administration. These findings suggest ATP13A2 may be a key protein involved in gene-environment interactions that contribute to neurodegenerative conditions. In the present study, two cohorts of mice were treated with a zinc chloride solution. In the first cohort, two-four month old wildtype (WT) and 13a2 mice received four subcutaneous injections over the course of 14 days of 20 mg/kg zinc chloride or vehicle. Soluble and insoluble aSyn levels were then

determined in the dorsal and ventral midbrain. In the second cohort WT, 13a2, aSyn overexpressing (aSyn), and double mutant 13a2-aSyn mice were administered a low dose of zinc chloride solution (1 mg/kg) by oral gavage chronically twice a week for four months beginning at two months of age. At six months of age, cathepsin D, p62, and LAMP1 expression levels were measured in the striatum, ventral midbrain, and cortex. Results from the first cohort show that soluble aSyn levels were significantly increased in the dorsal midbrain but not ventral midbrain in 13a2 mice receiving zinc compared to vehicle-treated WT. No changes in insoluble aSyn were detected in either region. In the second cohort, zinc-treated double mutant 13a2-aSyn mice had significantly increased levels of LAMP1 and p62 and significantly decreased levels of cathepsin D in the striatum compared to zinc-treated WT mice. These data indicate loss of ATP13A2 function in vivo leads to increased sensitivity to zinc and region specific alterations in aSyn accumulation and lysosomal function.

Title: Nuclear translocation of SIRT2 induced by Cdk5 dependent phosphorylation promotes the dopaminergic neuron death in Parkinson's disease

Authors: ***J. YAN**, P. ZHANG, F. HE, F. JIAO, Q. WANG, L. CHEN, Q. ZHANG, B. TIAN; Dept. of Neurobiology,Tongji Med. Sch., Huazhong Univ. of Sci. and Technol., Hubei, China

Abstract: Parkinson’s disease (PD), commonly known as a secondary degenerative disease of the central nervous system (CNS),is characterized with the progressive loss of dopaminergic (DA) neurons within the SNpc (substantia nigra pars compacta). NAD-dependent protein deacetylases Sirtuin 2 (SIRT2), which mediates multiple cellular pathways by deacetylating its various substrates, has been extensively investigated in Parkinson’s disease. Although numerous

publications were shown SIRT2 deletion has beneficial effects against dopaminergic neuron loss in the 1-methyl-4-phenyl-1, 2, 5, 6-tetrahydropyrine (MPTP) model of Parkinson's disease, the precisely mechanisms under SIRT2 mediates neuronal death have remained largely unknown. Here, we show that ablating of SIRT2 could rescue PD, TH positive neurons within SNpc and behavior test were performed in SIRT2 KO (knockout) mice after systemic administration of MPTP via the intraperitoneal route and the α-synuclein-A30P*A53T double mutant transgenic mice of PD lacking of SIRT2. The mRNA and total protein level of SIRT2 were not altered in animal and cell model of PD detected by RT-PCR and Western Blot. Importantly, SIRT2 translocate from cytoplasm to nucleus in Parkinson's disease cell model and animal model, as well as the nuclear translocation SIRT2 could promotes neuronal death. Furthermore, Cdk5 (Cyclin-Dependent Kinase 5) was required for the translocation of SIRT2 by the Ser331 and Ser335 sites phosphorylation. On the basis of our data, a short peptide named Myr-SIRT2$_{328-339}$, targeting competitive inhibition of Cdk5-dependent Ser331 and Ser335 phosphorylation within SIRT2, was designed and conjugated myristic to ensure its cell-penetrating ability. Unsurprisingly, Myr-SIRT2$_{328-339}$ could obviously decrease the mortality of primary culture neurons on the condition that MPP^+ treated. In conclusion,these results implicate a novel mechanism of regulating neuronal death by Cdk5-dependent nuclear-cytoplasmic shuttling of SIRT2 in the progression of Parkinson's disease. Future studies aimed at further elucidating the exact mechanistic action of the nuclear localization of SIRT2 are essential for promoting the dopaminergic neuronal death, thus providing additionally therapeutic target in PD.

Title: Dysregulation of protein phosphatase 2A in dementia with lewy bodies

Authors: H.-J. PARK[1], K.-W. LEE[1], E. PARK[1], S. OH[1], R. YAN[1], J. ZHANG[1], T. BEACH[2], C. ADLER[3], M. VORONKOV[4], S. BRAITHWAITE[4], J. STOCK[4,5], *M. M. MOURADIAN[1]; [1]Neurol., Rutgers-Robert Wood Johnson Med. Sch., Piscataway, NJ; [2]Banner Sun Hlth. Res. Inst., Sun City, AZ; [3]Mayo Clin., Scottsdale, AZ; [4]Signum Biosci., Princeton, NJ; [5]Mol. Biol., Princeton Univ., Princeton, NJ

Abstract: Protein phosphatase 2A (PP2A) functions as a master regulator of cellular phosphoregulatory networks in the brain, controlling key processes required for protein homeostasis and cell survival. The heterotrimeric holoenzyme is composed of a highly conserved catalytic C subunit, a scaffold-like A subunit, and one of several regulatory B subunits that confer substrate specificity. The assembly and activity of PP2A is regulated by reversible carboxyl methylation of the C subunit. α-Synuclein, which misfolds and aggregates in hallmark pathologic lesions of Dementia with Lewy Bodies (DLB), is phosphorylated at Ser_{129}, and PP2A containing a B55α subunit is a major phospho-Ser_{129} phosphatase. To investigate the possibility that PP2A dysregulation could play a role in the pathogenesis of DLB, we have compared the state of PP2A methylation, as well as the expression of its methylating enzyme, leucine carboxyl methyltransferase (LCMT-1), and demethylating enzyme, protein phosphatase methylesterase (PME-1), in postmortem brain tissues from 8 DLB cases and an equal number of age-matched non-neurological controls. Mean age at death was 82 ± 2.6 years for DLB and 84 ± 2.1 years for Controls. Postmortem interval was ≤ 3 hours in all subjects. Mean Mini Mental State Examination scores were 8.8 ± 3.1 in DLB and 27.1 ± 0.8 in Controls ($p < 0.01$). Neuropathological stage of α-synucleinopathy assigned according to the Unified Staging System for Lewy Body Disorders showed all DLB cases to be in stage 4, and all the Controls were in stage zero. Concomitant Alzheimer pathology was also present. Immunohistochemical studies showed that LCMT-1 was significantly reduced in both frontal cortex and substantia nigra of DLB cases compared to Controls, while PME-1 was not significantly altered. This was associated with a reduction in the ratio of methylated PP2A to demethylated PP2A in DLB. These findings support the hypothesis that PP2A dysregulation in α-synucleinopathies may contribute to the accumulation of hyperphosphorylated α-synuclein and to the disease process, raising the possibility that pharmacological means to enhance PP2A phosphatase activity may be a useful disease modifying therapeutic approach.

Title: characterization of n370s gba1-PD ips cells derived human dopaminergic neurons

Authors: *S. YUN, H. KO;
Neurol., Johns Hopkin Med., Lutherville Timonium, MD

Abstract: Mutations in glucocerebrosidase1 (GBA1) are the most common genetic risk factor for development of Parkinson's disease. Here we generate several iPSC cell lines from sporadic PD patients with or without N370S GBA1 mutation, the most frequent mutation. Employing a floor-plate-based strategy, we differentiate the iPSC cell lines into human dopaminergic (DA) neurons. Human dopaminergic neurons derived from N370S GBA1-PD iPSCs exhibit several biochemical and cellular defects including decreased GBA1 protein levels and enzyme activity and subsequent accumulation of α-synuclein, mitochondrial defects, reduced lysosomal β-galactosidase enzymes activity, as well as susceptibility to α-synuclein preformed fibrils (PFFs) induced LB/LB-like pathology and human DA neuron death. Moreover, the levels of total glucosylceramide and glucosylsphingosine, substrates of GBA1, are increased in N370S GBA1-PD iPSCs derived human DA neurons as assessed by quantitative lipidomic analysis. Strikingly, overexpression of wild type GBA1 reverses such biochemical and cellular defects observed in N370S GBA1-PD iPSCs derived human neurons. We are currently conducting RNAseq to identify changes in transcriptome due to N370S GBA1 mutation. Taken together, the N370S GBA1-PD iPSCs recapitulate biochemical and cellular phenotypes of GBA associated PD and provide unlimited, stable and genetically tractable sources for understating molecular mechanisms of PD due to GBA mutation and a drug-screening platform for preclinical drug discovery for the GBA-associated PD therapy.

Title: Alterations in ganglioside biosynthesis and content in Parkinson's disease and role in modulating vulnerability for neurodegeneration

Authors: *M. VERMA[1], S. JACKSON[2], T. N. SEYFRIED[3], H.-S. CHOI[3], Z. AKGOC[3], A. LYNN[3], J. S. SCHNEIDER[1];
[1]Thomas Jefferson Univ., Philadelphia, PA; [2]Thermo Fisher Scientific, South San Francisco, CA; [3]Boston Col., Chestnut Hill, MA

Abstract: We have previously shown that administration of GM1 ganglioside to Parkinson's disease (PD) patients results in a lower than expected rate of symptom progression. Decreased expression of GM1 in PD substantia nigra (SN) could increase the vulnerability of dopamine (DA) neurons to damage and administration of GM1 may have restored a sufficient amount of GM1 to enhance functionality and stabilize/protect these neurons. Alterations in ganglioside biosynthesis and expression have been observed in association with aging and may occur in some neurodegenerative diseases (such as Huntington's disease). The extent to which such changes occur in the PD brain are unclear as is the potential role that such changes might play in enhancing the vulnerability of DA neurons to neurodegeneration in response to various stressors. The expression of various glycosyltranferases and sialyltransfereases involved in ganglioside biosynthesis (as well as other genes representing various biochemical pathways associated with glycolipid synthesis and metabolism and select additional genes of potential relevance to PD and neuroprotection) was examined by laser capture microdissection of substantia nigra (SN) DA neurons followed by RNA extraction, generation of RNA amplicon libraries for use with a custom Ampliseq glycomics panel and Next-Gen sequencing using the Ion PGM System. Numerous genes were highly down-regulated in PD DA neurons (compared to age/sex-matched normal control DA neurons) and included *B3Galt4, St8Sia5, St3Gal2, FGF2, FGFR1*. qPCR also showed decreased *B3Galt4* and *St3Gal2* expression in PD SN extracts. Analysis of total gangliosides and ganglioside distribution in PD and control SN showed total ganglioside content, GD1a, GD1b, and GT1b to be significantly decreased in PD SN compared to control. GM1 was also decreased but this did not reach statistical significance. We then examined the extent to which a decrease in *B3Galt4* expression might enhance vulnerability to a low level exposure of a potential toxicant. Exposure of differentiated SK-N-SH DAergic cells to *B3galt4* siRNA significantly decreased GM1 expression and resulted in significant cell death in response to an exposure (10μM MPP^+) that previously resulted in no cell loss. These results suggest that the glycolipid defect in SN DA neurons in PD may be more extensive than previously thought and that changes to the integrity of glycolipids in the PD brain may play an important role in the pathogenesis of PD.

Abstract: A hallmark of Parkinson's disease is the progressive loss of nigrostriatal dopaminergic neurons. We derived human neuroepithelial cells from induced pluripotent stem cells and successfully differentiated them into dopaminergic neurons within phase-guided, three-dimensional microfluidic cell culture bioreactors. After 30 days of differentiation within the microfluidic bioreactors, in situ morphological, immunocytochemical and calcium imaging confirmed the presence of dopaminergic neurons that were spontaneously electrophysiologically active, a characteristic feature of nigrostriatal dopaminergic neurons in vivo. Differentiation was as efficient as in macroscopic culture, with up to 19% of differentiated neurons immunoreactive for tyrosine hydroxylase, the penultimate enzyme in the synthesis of dopamine. This new microfluidic cell culture model integrates the latest innovations in developmental biology and microfluidic cell culture to generate a biologically realistic and economically efficient route to personalised drug discovery for Parkinson's disease.

Title: Increased Kv2.1 channel expression contributes to nigrostriatal degeneration in MPTP induced Parkinson’s disease model

Authors: R.-Y. CHAO[1], C.-H. CHENG[1], *P.-C. CHEN[2];
[1]Physiol., Natinal Cheng Kung Univ., Tainan, Taiwan; [2]Physiol., Natl. Cheng Kung Univ., Tainan, Taiwan

Abstract: Parkinson's disease is due to the loss of dopaminergic neurons in the substantia nigra pars compacta (SNpc DA neuron) and the degeneration of dopaminergic axon terminals the dorsal stratum. Kv2.1, a voltage gated potassium channel enhanced K^+ efflux has been shown to be an essential mediator in programmed cell death and oxidative aggregation of Kv2.1 may be a key event in both healthy aging and neurodegenerative diseases. Although Kv2.1 channel has not been reported in the regulation of pacemaker activity in SNpc dopamine neurons, Kv2.1 channel expression can be detected in DA neurons across postnatal development. First, we asked whether Kv2.1 channel is involved in the nigrostriatal degeneration using 1-metyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) induced Parkinson's disease mouse model. Mice were injected with 30 mg/kg of MPTP for 5 days, withdrawal for 7 days and sacrificed at day 7. We observed the loss of DA neurons in SNpc and DA axon terminals in the striatum. Interestingly, there was an increase of Kv2.1 channel expression in the SNpc and striatum after MPTP injection. Quantitative PCR analysis revealed that no changes in mRNA level between the vehicle and MPTP groups. Then, for the distribution of Kv2.1 channels in the striatum or SNpc, vehicle treated mice had more punctate staining of Kv2.1 channel in both the SNpc and stratum than MPTP treated mice. To characterize what type of neuron express Kv2.1 channels, we co-stained Kv2.1 and DARPP-32 which is the marker for striatal medium spiny neurons. Co-staining results indicated Kv2.1 channel is located in medium spiny neurons. Next, to understand whether this increase of Kv2.1 channel is necessary for MPTP-induced nigorstriatal degeneration, mice pre-treated with Kv2.1 blocker (0.11mg/kg, Guangxitoxin 1E, GxTx) followed by MPTP injection showed more DA neurons in the SNpc and DA axon terminal in the striatum using immunoblotting and immunostaining assays, suggesting that inhibition of Kv2.1 channel protects DA neurons from MPTP toxicity. In parallel, MPP^+ dose dependently increased the expression of Kv2.1 channel in dopaminergic cell lines (MN9D, SY5Y) and primary cortical neuron culture. We confirmed the results by caspase 3 immunostaining and cell viability assay. Also, pre-treatment with GxTx inhibited MPP^+ induced Kv2.1 channel increase in MN9D cells. In conclusion, our results suggest that increased expression of Kv2.1 channel contributes to nigrostriatal degeneration. In the future, we will primarily focus on the investigation of underlying mechanism by which MPTP regulated the increase of Kv2.1 channel expression and continue to improve the quality for the data.

Title: A possible involvement of TRPM7 in the 6-hydroxy-dopamine model of Parkinsons disease

Authors: *L. M. DATI[1], H. ULRICH[1], H.-S. SUN[2], Z.-P. FENG[2], L. BRITTO[1];
[1]Univ. of Sao Paulo, Sao Paulo, Brazil; [2]Univ. of Toronto, Toronto, ON, Canada

Abstract: Parkinson´s disease (PD) involves a loss of dopaminergic neurons of the substantia nigra, which produces marked motor and cognitive disorders. PD has been studied with several approaches, including animal models such as the 6-OH-dopamine intrastriatal injection. Since transient receptor potential TRPM7 channels have been recently demonstrated to be involved in some neurodegeneration conditions, we sought to investigate a possible participation of TRPM7 in the pathophysiology of PD-like condition in the mouse, this receptor is binding with G-protein, so is important to regulated the cell. This work used techniques by means of immunohistochemistry and Western blotting. Tyrosine-hydroxylase immunolabeling in wild-type mice (C57BL/6) was reduced by about 50% both in the striatum and the substantia nigra on the side ipsilateral to the 6-OH-dopamine injection in relation to the contralateral side, injected with saline. TRPM7 is increased in both the striatum (ca. 80%, $p<0.005$) and substantia nigra (ca. 50%, $p<0.005$) after injections of 6-OHDA. We have then used a TRPM7 inhibitor, carvacrol (40mg/Kg, i.p.), the animals had 30 minutes after the put carvacrol for admintration of 6-OHDA, and evaluated tyrosine-hydroxylase expression in both control and 6-OH-dopamine-injected animals. The results showed that, in the striatum, the reduction of dopaminergic innervation observed in control animals was markedly attenuated (ca. 72%) in carvacrol-treated mice. The same was observed for the substantia nigra, as the typical reduction of the number of tyrosine-hydroxylase positive neurons after 6-OH-dopamine was not significant in carvacrol-treated mice (attenuation of ca. 85%). This compare is about group carvacrol with 6-OHDA for saline anda 6-OHDA. When compare the group carvacrol with 6-OHDA, it's possible see that in striatun has the increased about 17%, but in substancia nigra is decreased about 13%, this not different the control but is different with group saline.In order to preliminarily investigate the mechanisms of the carvacrol-induced neuroprotection, we analyzed the expression of caspase 3 with the same protocols. There was an increase of caspase 3 expression of about 90% ($p<0.005$) in both the striatum and the substantia nigra after 6-OH-dopamine injections, whereas the carvacrol-treated

mice did not show appreciable increases of caspase 3, so this group stay similar the control. These results suggest that TRPM7 is involved in the pathophysiology of the 6-OH-dopamine model of Parkinson´s disease, possibly by increasing caspase 3 levels.

Title: Neuroplasticity induced by acrobatic exercise in a rat model of Parkinson's disease.

Authors: *R. S. PIRES[1], N. R. SANTIAGO[1], Q. R. S. G. FERRAREZI[1], R. O. JACOB[1], C. C. REAL[2], L. R. G. BRITTO[2];

Abstract: Parkinson's disease (PD) is a neurodegenerative and progressive disease that promotes motor, cognitive and emotional deficits that are ameliorated with treadmill and wheel running exercise. Nevertheless, little is known about the effects of acrobatic exercise, which involves complex motor tasks requiring intense activation of basal nuclei-thalamus-cortical circuit, which is compromised in PD. Therefore, our objective was to analyze neuroprotective effects and plasticity changes in motor regions of the brain of rats submitted to unilateral 6-hydroxydopamine (6-OHDA) PD model and acrobatic exercise protocol. Forty-eight animals were divided into 2 groups, namely Parkinson's (PD) and Control-saline (SAL), and each one was subdivided into acrobatic (AC) and sedentary (SED). The AC moved through a circuit of obstacles 5 times/day, 3 days/week for 4 weeks. One month after starting the training, their brains were removed for immunohistochemistry and Western blotting assays to analyze the expression of microtubule-associated 2 (MAP2), synaptophysin (SYP) and tyrosine hydroxylase

(TH) in the prefrontal cortex, motor cortex, dorsolateral and dorsomedial striatum and substantia nigra pars compacta (SNc). Statistical analyses were performed using one-way ANOVA with the Bonferroni *post hoc* test. PD+SED group showed a decrease in the percentage of TH-positive cells in the SNc (ca. 48%, $p < 0.0001$) when compared to SAL+SED, but the PD+AC group had a higher number of TH+ cells (ca. 40%, $p<0.0001$) compared to SED. In the striatum, 6-OHDA produced a significant TH, MAP2 and SYP decrease in the dorsomedial (ca. 30%, $p<0.0001$; ca. 31%, $p < 0.0001$; ca. 29%; $p<0.0001$; respectively) and dorsolateral striatum in the PD+SED (ca. 29%, $p < 0.0001$; ca. 47 %, $p<0.0001$; ca. 35%, $p<0.0001$; respectively) compared to SAL+SED. However, PD+AC showed a TH, MAP2 and SYP increase in the dorsomedial (ca. 17%, $p<0.0001$; ca. 12%, $p<0.0001$; ca. 11%, $p<0.01$; respectively) and dorsolateral (TH- ca. 17%, $p<0.0001$ and MAP2 - ca. 38%, $p< 0.0001$) areas compared to PD+SED. In the motor cortex and prefrontal cortex, both PD+SED and PD+AC revealed no changes in the MAP2 and SYP expression compared to SAL+SED and SAL+AC. In conclusion, our data suggested that four weeks of AC exercise induced a neural circuit reorganization, mainly in nigrostriatal areas that are injured in PD.

Title: 6-hydroxydopamine- and L-DOPA-induced shifts in striatal monoamine transporter function in L-DOPA-primed, hemi-parkinsonian rats

Authors: *M. CONTI, S. MEADOWS, J. GOLD, N. PALUMBO, J. HALLMARK, D. WERNER, C. BISHOP;
Psychology, Binghamton Univ., Binghamton, NY

Abstract: Motor symptoms resulting from dopamine (DA) cell loss seen in Parkinson’s disease are typically treated with the DA precursor L-DOPA. However, chronic treatment usually results in abnormal involuntary movements (AIMs) referred to as L-DOPA-induced dyskinesia (LID). Growing evidence suggests that mechanisms underlying LID involve interactions between the remaining DA system and serotonin (5-HT) and norepinephrine (NE) systems. Specifically, 5-HT and NE transporters (SERT and NET, respectively) gain function in L-DOPA-derived DA uptake when DA transporter (DAT) levels are low. Recently, our lab has shown that DAT,

SERT, and NET inhibition with monoamine transporter-specific blockers differentially modulate LID expression, with SERT blockade having the greatest effect. Although a functional shift can be inferred from behavioral measures, a structural shift in striatal DAT, SERT, and NET expression has not been well characterized. Therefore, the current experiment sought to determine how severe DA loss and subsequent L-DOPA treatment affected striatal DAT, SERT, and NET levels in unilateral sham- or 6-OHDA-lesioned Sprague-Dawley rats. After a 3 week recovery period, rats were sorted into equal groups based on motor performance. Rats were then primed with vehicle or L-DOPA (12 mg/kg + benserazide 15 mg/kg; s.c.) and monitored for AIMs expression. After a 1 week washout period, rats were given daily vehicle or L-DOPA (6 mg/kg) for 2 weeks while being monitored for AIMs expression and off treatment motor performance. One hour after rats received their last respective treatment, lesioned striatal tissue was taken for whole cell western blot analysis of total DAT, SERT, and NET expression. Behaviorally, DA-lesioned rats had worse motor performance than sham-lesioned rats and only the L-DOPA treated, DA-lesioned group exhibited significant LID. Lesion-induced DAT loss mirrored motor deficit while SERT and NET expression was unaffected by DA depletion or L-DOPA treatment. Interestingly, SERT:DAT and NET:DAT increased in the L-DOPA treated, DA-lesioned group which significantly correlated with LID severity. Overall, severe DA loss and L-DOPA treatment appear to functionally promote SERT and NET without affecting cellular expression in the dyskinetic striatum.

Title: Neuroprotective role of Osmotin in alpha-synuclein induced neuropathology via AMPK activated signaling cascade.

Authors: ***M. JO**, M. KHAN, M. SOHAIL, M. KIM;
Neurobio. Lab., Jinju, Korea, Republic of

Abstract: Studies of neurodegenerative diseases have focused on the physiological and pathological abnormalities of specific neuronal cell populations. Abnormal neuronal aggregation

of α-synuclein is implicated in the development of many neurological disorders. Natural products have been a focus of scientific research as therapeutic agent for prevention and treatment of neuro-degenerative disease. Osmotin is a pathogenesis-related (PR) plant protein is a homolog of the mammalian adiponectin hormone. Previously it's been reported that Adiponectin negatively regulate the pathogenesis of α-synucleinopathies in an animal model. In present study an in vitro model over expressing a-synuclein in SH-SY5Y human neuroblastoma cells treated MPP+ to mimic α-synucleiopathy been designed. Osmotin treatment shows diminution in α-synuclein overexpression as compared to untreated samples. AMPK is a master regulator believed to play a critical role in the control of energy homeostasis and survival of neurons. Present study shows that osmotin restores AMPK activity interrupted by enhanced expression of mTOR associated proteins like LKB1 and RPTOR protein responsible for neurotoxicity of α-synuclein in disease model. Osmotin not only reduced α-synuclein expression but also enhances cell survival and synaptic neurotransmission through enhanced dopamine sysnthesis. Present study elaborates therapeutic potential of osmotin against α-synuclein induced neuropathy by activation of AMPK and its associated downstream signaling proteins.

Title: Behavioural effects of sodium benzoate, a cinnamon metabolite, on the 6-hydroxydopamine rat model of parkinson's disease.

Authors: ***M. K. SHAMMAS**[1], R. T. KENNEDY[2];
[1]Neurosci., [2]Chem. and Pharmacol., Univ. of Michigan, Ann Arbor, MI

Abstract: Parkinson's disease (PD) is the second most common neurodegenerative disorder after Alzheimer's. Its main treatment, levodopa (L-DOPA), has side effects, most prominently dyskinesia, that become worse over time, and in some cases become more intolerable than the disease itself. A recent study (J Neuroimmune Pharmacol. 2014; 9:569-81) has shown that sodium benzoate (NaB), a metabolite of cinnamon, plays a neuroprotective role in a mouse model of PD. In the current study I examined the effect of NaB treatment on the 6-hydroxydopamine (6-OHDA) rat model of PD. The results show that rats who had NaB (150-300 mg/kg/day) in their water continuously beginning one week before the 6-OHDA lesion developed significantly less L-DOPA-induced dyskinesia (LID) as measured by the Abnormal

Involuntary Movements (AIMs) scale after an acute injection of L-DOPA (25 mg/kg) and benserazide (15 mg/kg, i.p.) than rats who had regular water. Also, the progression of LID between the first and second injections of L-DOPA was significantly lower in the group receiving NaB during the period between the injections than in the group that received regular water. To assess limb functionality and Parkinsonism, I measured the performance of both groups on the stepping test. The NaB-treated group performed significantly better, indicating a possible neuroprotective or therapeutic effect of NaB. Finally, while previous findings were ambiguous about this subject, I show that LID due to high doses of L-DOPA correlates very well with the number of amphetamine (5 mg/kg, i.p.)-induced rotations in untreated 6-OHDA rats, but not in NaB rats.

Title: Distribution of beta-synuclein in dementia with Lewy bodies brain tissues

Authors: T. EVANS, K. COWAN, *O. ANICHTCHIK;
Plymouth Univ., Plymouth, United Kingdom

Abstract: Dementia with Lewy bodies (DLB) is the second most frequent neurodegenerative dementia characterised by accumulation of aggregated fibrils of α-synuclein in limbic areas and forebrain. Synucleins (α-, β-, γ-) are small pre-synaptic proteins with a similar distribution in the brain however, unlike α-synuclein, β-synuclein is not thought to have aggregation properties and has been shown to prevent α-synuclein aggregation *in vitro* and *in vivo*. Regional changes in β-synuclein expression levels, in addition to observations of structural synaptic alternations and small α-synuclein aggregates, have been observed in the brains of DLB patients suggesting pre-synaptic changes may be among events preceding neuronal degeneration. We have shown previously that α-synuclein aggregation causes early synaptic dysfunction in the mouse model of Parkinson’s disease (PD), and morphological disorganisation of synaptic proteins in post-mortem

tissues of early PD patients. Here we were asking whether α-synuclein-associated synaptic protein disorganisation is also present in DLB, and whether β-synuclein distribution in DLB brain is altered in relation to the α-synuclein aggregation burden. We have examined frontal, occipital cortex and the hippocampus in patients with DLB with less than 5 years disease duration and age-matched controls. Tissues were obtained from the Human Brain Bank of Parkinson's disease (UK) and from Brains for Dementia Research Brain Banks (UK). Immunohistochemical staining for full length and oligomeric α-synuclein, β-synuclein, SNARE proteins (synaptobrevin/VAMP2, SNAP25, syntaxin) and lysosomal markers were performed on paraffin-embedded sections, and semi-quantitative Western blotting was done to examine changes in protein levels. We have identified close association between β-synuclein and SNARE proteins in the cortical areas, but not in the hippocampus. In addition, we have detected an increase of β-synuclein levels in the frontal cortex, while this was reversed in the occipital cortex. The pilot data indicated that levels of β-synuclein were inversely correlated with levels of oligomeric α-synuclein. These findings will be discussed in relation to the pathophysiology of synaptic dysfunction in DLB.

Title: Stimulation amplitude-dependent modulation of neuronal activity around chronically implanted thalamic deep brain stimulation arrays

Authors: ***M. D. JOHNSON**, Y. XIAO;
Biomed. Engin., Univ. of Minnesota, Minneapolis, MN

Abstract: There is a strong clinical need for implantable deep brain stimulation (DBS) lead designs that allow for better steering of electric fields within the brain, especially in cases where stimulation through a misplaced DBS lead results in low-threshold side-effects. Radially segmented DBS arrays (DBSAs) have potential to rescue therapy in such cases, but the electrophysiolgical effects of directing current within the brain through these arrays remain

relatively unexplored. In this study, we investigated how stimulation amplitude affects neuronal firing rate and pattern changes around a motor thalamic DBSA. A DBSA with 8 rows of 4 radial electrodes was implanted unilaterally in the motor thalamus in two non-human primate. A single row of electrodes was selected where each contact performed 3 sets of 100Hz stimulations at 350μA, 250μA and 150μA, while microelectrode recordings were made in a grid pattern around the DBSA. Peri-stimulus time histograms were compared between DBS and pre-DBS periods (30-60s) and grouped into nine categories based on firing pattern modulation (FPM) and change in firing rate. An entropy-based method was used to quantify the degree of FPM and determine instances of significant modulation. For both thalamic DBSA implants, thalamic neurons sampled around the lead showed firing pattern and rate modulation that were sparsely distributed and were not confined to regions in the immediate proximity of the DBSA. Higher stimulation amplitudes resulted in greater change in firing pattern (i.e. increased regularity) in the subgroup of cells that showed significant FPM under at least one stimulation amplitude. Interestingly, only 3.25% (±3.8%) of DBS pulses produced a phase-locked spike in cells with a significant excitatory FPM. While computational models often predict uniform modulation of neuronal spike activity around a DBS lead, this study demonstrates that the volume of neuronal modulation is in fact sparsely represented. Moreover, while neuronal activity becomes time-locked to DBS, only a small fraction of stimulus pulses actually result in a phase-locked spike. This work will help inform the next generation of computational models of DBS and provide insight for future implant designs.

Title: Effect of parkinsonism and deep brain stimulation on neural oscillations and phase-amplitude coupling within the motor cortex, subthalamic nucleus and globus pallidus

Authors: *D. ESCOBAR SANABRIA[1], L. A. JOHNSON[1], J. ZHANG[1], S. NEBECK[1], M. D. JOHNSON[2], G. F. MOLNAR[1], K. B. BAKER[1], J. L. VITEK[1];
[1]Neurol., [2]Biomed. Engin., Univ. of Minnesota, Minneapolis, MN

Abstract: A neurophysiological biomarker that reflects Parkinson's disease (PD) severity or motor symptoms is still being debated. Alterations in neural oscillations across sites in the basal ganglia-thalamocortical network and in various low- and high-frequency bands have been implicated in the pathophysiology of PD and therapeutic mechanisms of deep brain stimulation (DBS). Recently, elevated coupling between the phase of low-frequency and the amplitude of high-frequency neural oscillations (phase-amplitude coupling, PAC) has been hypothesized to be a biomarker of PD severity and symptoms. It is not well understood, however, how oscillatory activity and PAC are altered from the normal to the parkinsonian condition, within different structures of the motor network, and during therapeutic DBS in different targets. In an effort to understand these alterations, we characterized oscillatory activity and PAC within the subthalamic nucleus (STN), globus pallidus (GP), and motor cortex (M1) of two rhesus macaques in the normal and parkinsonian conditions, and during therapeutic DBS. Each animal was implanted with a DBS lead in both STN and GPi and a Utah array in M1. The animals were rendered parkinsonian by systemic administration of the neurotoxin MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine). We analyzed data collected in the awake resting state and assessed both static measures and the temporal dynamics of oscillatory activity and PAC. Analysis showed that oscillations in single frequency bands within the studied brain structures did not differ between normal subjects. In the parkinsonian state, however, we observed significant changes in oscillatory activity and PAC which varied across animals, suggesting there may be subject-specific signatures of network dysfunction. In particular, PAC emerged in the M1 (~25 Hz for phase, ~50 Hz for amplitude) of one subject but in the GP (~10 Hz for phase, ~200 Hz for amplitude) of the other. In the first subject, STN-DBS suppressed PAC in M1 but GPi DBS did not, whereas in the second subject, GPi-DBS suppressed PAC in GP but STN-DBS enhanced it. These results suggest that PAC may manifest in different structures of the basal ganglia-thalamocortical network in the parkinsonian condition. This study also highlights that the relationship between PAC and parkinsonian motor signs and the role of PAC in mediating the therapeutic effects of DBS remain unclear.

Title: Neuro-pathophysiology of SMA-M1 single unit activity during visually guided reach in the progressive MPTP nonhuman primate model of Parkinson's disease

Authors: *B. CAMPBELL[1], C. M. HENDRIX[1], B. J. TITTLE[1], Y. ADIBI[1], Z. M. WEINSTOCK[2], G. F. MOLNAR[1], M. D. JOHNSON[3], K. B. BAKER[1], J. L. VITEK[1]; [1]Neurol., [2]Col. of Biol. Sci., [3]Biomed. Engin., Univ. of Minnesota, Minneapolis, MN

Abstract: Motor signs in Parkinson's disease (PD) are primarily related to pathophysiological changes in basal ganglia thalamo-cortical (BGTC) motor circuitry affecting the kinematics of visually guided movement. However, the underlying mechanisms and changes in cortical neural activity with disease severity are not well understood. This study characterized task specific changes in behavior and neuronal activity in SMA and M1 during a visually guided movement in the MPTP NHP. Concurrent MER, (paired-SU within and across M1-SMA cortical sites) and task behaviors, (reach kinematics and eye movements) were recorded. Compared to the normal state, eye movements in the parkinsonian state showed an increase in the occurrence and duration of eye fixation prior to presentation of the visual go-cue and followed by an increase in time-locked saccades towards the visual target after the go-cue. In contrast, initiation of hand movement after go-cue was delayed in the parkinsonian state. In addition, the reach kinematics were also impaired resulting in longer and more variable reach times, decreased accuracy, and degraded stereotypy in reach paths. Perievent histograms, auto-correlograms, and cross-correlograms of SU activity time-locked to task behaviors showed a decrease in event related modulation and correlated paired-SU activity (both magnitude and timing). Kinematics of visually guided reach behavior and related cortical activity presented task specific changes in the parkinsonian state. Saccade initiation towards the target were faster and closely time-locked to the onset of the go-cue and may reflect difficulty in suppressing reflexive saccades towards external visual cues. Reach onset, on the other hand, was delayed relative to the go-cue. Disinhibition of saccadic movement coupled with prolonged reaction times may reflect a compensatory strategy of engaging sequential, stepwise mechanisms during the visuomotor reach. Finally, task related cortical activity in M1 and SMA also changed in PD resulting in a reduction in task related modulation and increased variability in timing relative to task events. A decrease in time-locked neural modulation in PD coupled with degradation in overall visuomotor coordination is consistent with a model of PD dysfunction that accounts for changes in selective firing patterns, suppression of non-selective firing patterns, and the temporal relationships of neural activity within cortical-cortical and across the thalamo-cortical motor pathways.

Title: Improved spatial resolution of local field potentials with deep brain stimulation arrays in the globus pallidus and subthalamic nucleus

Authors: *S. ZHANG, M. D. JOHNSON;
Univ. of Minnesota, Minneapolis, MN

Abstract: The basal ganglia nuclei are known to have a functional topography composed of motor subcircuits and oscillatory networks that are likely to be critically important for the successful application of closed-loop deep brain stimulation (DBS) therapy to treat Parkinson's disease. To accurately measure oscillatory dynamics using local field potentials (LFPs), the bipolar pair of recording electrodes should match the geometry of the target neural dipoles so that the electrodes do not shunt the underlying heterogeneity of sinks and sources. We hypothesized that there is spatially heterogeneous oscillatory activity in the globus pallidus (GPe/GPi) and subthalamic nucleus (STN) at a spatial scale smaller than that observable with conventional clinical DBS leads. In this study, DBS arrays (DBSAs), with 8 rows of 4 radially-oriented electrodes, were chronically implanted in the GPe/GPi and in the STN in a non-human primate. Electrodes on the GPe/GPi (and STN) arrays were 360μm x 470μm (350μm x 360μm) with axial pitch given by 572 μm (750 μm) and circumferential pitch given by 471 μm for both arrays. Resting-state LFP recordings were collected across both arrays, filtered in the low beta band (12-20 Hz), and current source density was calculated. Multiple oscillatory dipoles were found across both DBS arrays. Notably, when simulating LFP recordings through a conventional DBS lead with four virtual cylindrical macroelectrodes - i.e. by shorting two rows of electrodes along the DBS array and taking the differential between shorted row pairs - oscillatory dipoles were not observed in the STN and two oscillatory dipoles were found for the GPe/GPi lead near the border between nuclei. Additionally, the differential LFP signal amplitude was 4x larger between individual electrodes around or along the DBS array than in the case of the differential signal between two virtual macroelectrodes. Together, the data suggest that closed-loop DBS will benefit from using DBS leads that consist of a more spatially refined distribution of electrodes along and around the lead shank.

Title: Low frequency modulations in the Supplementary Motor Area (SMA) and motor cortex (MC) in the MPTP nonhuman primate (NHP) model of Parkinson's disease.

Authors: *Y. ADIBI[1], C. HENDRIX[2], B. CAMPBELL[2], K. BAKER[2], J. L. VITEK[2];
[2]Neurol., [1]Univ. of Minnesota, Minneapolis, MN

Abstract: Changes in the basal ganglia thalamocortical motor circuit are thought to underlie the motor signs in Parkinson's disease. Although multiple studies have reported changes that occur in subcortical structures, little is known about changes in cortical neuronal activity. To further explore the changes that take place in these cortical motor areas, we recorded local field potentials (LFPs) in SMA and M1 in both normal and parkinsonian conditions. Oscillatory activity was analyzed through spectrograms during epochs of a controlled 8-target center-out reaching task. Spectrograms were aligned with the visual go-cue and averaged across trials. Low frequency (0-8 Hz) power increased in SMA and M1 following the go-cue in both conditions. Changes in power however, showed different patterns in the normal and parkinsonian state. Beta (13-30 Hz) desynchronization immediately followed the visual go-cue and was relatively more persistent in the naïve state as compared to PD. Furthermore, an increase in beta activity was observed following target touch coincident with upper limb freezing in the return movement. Differences in the patterning, manner of activation, and timing of return of LFP activity in the different frequency spectrums between the two cortical regions may be suggestive of area-specific biomarkers and indicative of cortical activity changes underlying the development of Parkinson's disease.

Title: Evolution in the modulation of passive responses in primary motor cortex during prolonged STN DBS in the parkinsonian monkey

Authors: *J. WANG[1], S. NEBECK[1], L. A. JOHNSON[1], J. ZHANG[1], M. D. JOHNSON[2], K. B. BAKER[1], G. F. MOLNAR[1], J. L. VITEK[1];
[1]Neurol., [2]Biomed. Engin., Univ. of Minnesota, Minneapolis, MN

Abstract: Deep brain stimulation (DBS) in the subthalamic nucleus (STN) has been a therapeutic treatment for Parkinsonian motor symptoms for decades. However, the effect of STN DBS on cell activity in the primary motor cortex (M1), a key nodal point in the basal ganglia-thalamo-cortical network, is not well understood. Moreover, the alteration of this neuronal activity during long-term STN DBS has not yet been explored. In the present study, the M1 neuronal responses to passive manipulation of arm during prolonged STN DBS were studied in the MPTP non-human primate (NHP) model of Parkinson's disease.
A NHP (female, 6kg) was implanted with an 8-contact scaled-down DBS lead in the STN and a 96-channel Utah array in the arm area of M1. Optimal stimulation contacts and parameters (0.2mA, 130Hz, 125μs) were determined by standard practice. Prolonged (4 hours) STN DBS was applied and the modified UPDRS (mUPDRS) score was assessed to confirm the efficacy of the DBS. Passive manipulations of elbow extension-flexion were performed pre, at multiple times during and post DBS. Single unit activities recorded from the array were sorted and analyzed to investigate the modulation of passive responses.
A 30-35% improvement of mUPDRS was observed during the prolonged DBS. A total of 53 well isolated single units were sorted from the array data. The modulation of passive responses in 91% of the units was altered by STN DBS. In the pre DBS baseline, 87% of the units were responsive to passive manipulation. During DBS, we observed changes in both the proportion of units responsive to passive manipulation and the depth of the modulation, and differences were observed between acute (minutes after DBS onset) and chronic changes. The number of

responsive units was slightly reduced immediately following onset of DBS. However, the proportion of units responsive to the passive manipulation increased to 94% at the end of the prolonged DBS. Differences between acute and chronic effects by DBS was also observed in the changes of modulation depth in ~30% of the units whose modulation of passive responses were altered by DBS. Overall, the modulation depths didn't increase until around one hour after DBS onset. The modulation of most of the units returned to the pre DBS level minutes after the DBS cessation.
The evolution of the modulation in the M1 neuronal responses to passive manipulation and the differences between the acute and chronic changes in modulation during the prolonged STN DBS observed in this study provide further understanding of the mechanism of DBS, as well as potential guidance to the selection of stimulation duration in future studies.

Title: Effect of levodopa on neuronal activity in primary motor cortex in the MPTP non-human primate model of Parkinson's disease

Authors: S. D. NEBECK[1], *L. A. JOHNSON[1], J. ZHANG[1], D. ESCOBAR[1], M. D. JOHNSON[2], G. MOLNAR[1], K. B. BAKER[1], J. L. VITEK[1];

Abstract: Primary motor cortex (M1) is a key component of the basal ganglia-thalamo-cortical (BGTC) network and likely plays a significant role in the manifestation of motor symptoms in Parkinson's disease (PD), yet relatively few studies have characterized the firing patterns of M1 neurons in PD. M1 is not only responsible for controlling voluntary limb movement, but is also integral to sensory processing of limb position and movement. It is believed that the loss of dopaminergic cells in PD disrupts this kinesthetic information processing leading to broadened receptive fields of cells throughout the BGTC network. In this study we examined the effect of levodopa, the most common medication used for treatment of PD symptoms, on neuronal

activity in M1 of two non-human primates (NHPs) rendered parkinsonian by systemic injections of the neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). A 96-channel microelectrode array was chronically implanted in the arm area of M1 to record populations of single units, and receptive fields were characterized by changes in firing rate in response to passive manipulation of the shoulder, elbow, and wrist joints. Recordings were made before and after levodopa administration. We hypothesized that dopaminergic therapy would serve to narrow receptive fields; that is, levodopa would reduce the number of joints to which a given neuron responds and improve sensory processing. Interestingly, spontaneous firing rates did not significantly change after levodopa. Analysis was further restricted to cells that were significantly modulated by manipulation of at least one joint in the on or off levodopa condition (NHP K: 71/75, NHP J: 53/71). Levodopa narrowed receptive fields (reduction in the number of joints to which cells responded) in 52% and 42% of the cells in NHPs K and J, respectively. Moreover, the degree of firing rate modulation and temporal dynamics of the response to a given joint manipulation differed between the on and off drug state, though the details of these differences were heterogeneous across the population. In summary, levodopa therapy that improves parkinsonian motor signs leads to narrowed receptive fields together with complex changes in M1 neuronal responses to passive joint articulation, supporting the hypothesis that kinesthetic information processing in M1 is disrupted in PD and improved by dopaminergic medication.

Title: STriatal-Enriched protein tyrosine Phosphatase (STEP) inhibitor TC-2153 improves aspects of cognitive dysfunction in aged Parkinsonian monkeys

Authors: *J. S. SCHNEIDER[1], C. WILLIAMS[1], P. LOMBROSO[2];
[1]Dept Pathol, Anat. & Cell Biol, Thomas Jefferson Univ., Philadelphia, PA; [2]Yale Univ. Sch. of Med., New Haven, CT

Abstract: Although Parkinson's disease (PD) is primarily a motor disorder, cognitive impairment is a common feature that can be present at all stages of the disease. Cognitive deficits in PD patients may be associated with dysfunction of multiple cortical and subcortical neurotransmitter systems and functional circuits, that include DAergic and non-DAergic systems. Thus, the benefits of DAergic replacement therapy on PD-related cognitive deficits have been inconsistent and alternative pharmacological targets and therapies are needed to better address cognitive dysfunction in PD patients. One such potential therapy involves modulation of STriatal-Enriched protein tyrosine Phosphatase (STEP). Elevated levels of STEP are associated with cognitive deficits in a variety of disorders and lowering STEP expression either genetically or pharmacologically significantly reduced cognitive deficits in aged rodents with cognitive impairment and in transgenic Alzheimer's disease models. We recently also observed significantly increased expression of STEP in hippocampus of aged rhesus macaques with cognitive impairment as well as a significant increase in STEP expression in the pre-frontal cortex of chronic MPTP-treated monkeys that expressed fronto-striatal cognitive deficits. In this study, we examined the extent to which the STEP inhibitor TC-2153 (3.75, 7.5, and 15 mg/kg) would attenuate cognitive impairments in aged rhesus monkeys previously exposed to the neurotoxin MPTP. Six males (approx. 26 years old) with prior chronic low dose MPTP exposure and with mild motor deficits and various cognitive deficits were used. TC-2153 had no effect on performance of a continuous performance attention task or a spatial working memory task (self ordered spatial search). In contrast, TC-2153 significantly decreased the number of trials needed to learn discrimination reversals in a compound discrimination learning task and improved new learning and memory of a discrimination learning-long term retrieval task. Administration of TC-2153 resulted in animals learning new discriminations significantly faster ($P < 0.01$) than during vehicle only sessions and long-term retention was significantly better ($P < 0.05$) if the learning occurred during TC-2153 administration. These results suggest that in this model, TC-2153 may not act as a general cognition enhancer but may improve new learning and recall of that newly learned information. Supported by the Michael J. Fox Foundation.

Abstract: Induced pluripotent stem cell (iPSC)-derived neurons present an opportunity for cell replacement strategies for neurodegenerative disorders such as Parkinson's disease (PD). Improvement in cell graft targeting, distribution and density can be key for disease modification. Our team has previously developed a MRI-compatible brain port system that we have demonstrated to be successful for intraoperative MRI (IMRI) delivery of viral vectors for gene therapy strategies. The aim of this study was to develop procedures suitable for real-time IMRI (RT-IMRI) targeting guidance to facilitate its application for intracerebral delivery of biologics, especially cells, as it decreases the targeting time. Dopamine neuroprogenitor neurospheres were used for these studies. We first performed a set of *in vitro* experiments to tailor the delivery hardware (e.g. cannula) and define a range of parameters to be applied (e.g. maximal timespan allowable between cell loading in the system and intracerebral injection) to ensure cell survival. Evidence of cell death, damage to neurospheres, and obstruction of the cannula were not observed after the cells were loaded and remained in the system for up to 2 hours; some cell-settling occurred, observed as the expelling of cylindrical neurosphere aggregates that could be easily dissociated. To assess if the process affects cell identity, a subset of the cells were plated after passing through the system and allowed to differentiate for 2 weeks. Immunostaining against tyrosine hydroxylase and βIII-tubulin confirmed that the dopaminergic identity of the cells was unchanged. Next we performed cell injections into a 0.6% agarose gel as a brain surrogate, to analyze patterns of cell distribution and associated intra-line pressure changes. We found that multiple distinct deposits could be easily delivered along the cannula tract and that the pressure reflected each bout of cell expulsion. Lastly, we evaluated the feasibility of applying the RT-IMRI system to deliver cells into the nonhuman primate brain, by injecting neurospheres labeled with Hoechst into the putamen nucleus. Experimental procedures were approved by the IACUC of the University at the Wisconsin-Madison. All efforts were made to minimize the number of animals used and to ameliorate any distress. Postmortem evaluation 2 weeks later showed abundant cell survival of Hoescht-positive cells that expressed nestin. Our results demonstrate that the RT-IMRI delivery system provides valuable guidance, monitoring, and visualization during intracerebral iPSC-derived neuron delivery that is also compatible with cell survival.

Title: Positron emission tomography imaging of cardiac neuroprotection induced by peroxisome proliferator-activated receptor gamma (PPARγ) activation

Authors: *J. SHULTZ[1,2], H. RESNIKOFF[1], V. BONDARENKO[1], J. HOLDEN[3], T. BARNHART[3], P. LAO[3], B. CHRISTIAN[3], J. NICKLES[3], C. F. MOORE[4], M. EMBORG[1,2,3]; [1]Wisconsin Natl. Primate Res. Ctr., [2]Cell. and Mol. Pathology Grad. Program, [3]Dept. of Med. Physics, [4]Dept. of Psychology, Univ. of Wisconsin - Madison, Madison, WI

Abstract: Loss of postganglionic sympathetic innervation to the heart is a characteristic pathology of cardiac dysautonomia in Parkinson's disease (PD); disease-modifying strategies are not available. Neuronal loss in PD is associated with inflammation and oxidative stress and can be mimicked in animals by dosing of the catecholaminergic neurotoxin 6-hyroxydopamine (6-OHDA). Interestingly, activation of the peroxisome proliferator-activated receptor gamma (PPARγ) decreases inflammatory response (microglial, macrophage) and production of reactive oxygen species. Here we report our studies with the PPARγ agonist pioglitazone in a nonhuman

primate model of cardiac dysautonomia induced by systemic dosing of 6-OHDA. We aimed to assess the neuroprotective efficacy of pioglitazone using positron emission tomography (PET) with radioligands specific to catecholaminergic innervation ([11C]meta-hydroxyephedrine, MHED), inflammation ([11C]peripheral benzodiazepine receptor 28, PBR28), and oxidative stress ([61Cu]diacetyl-bis(N(4))-methylthiosemicarbazone, ATSM). Ten adult, male rhesus monkeys received intravenous 6-OHDA (50mg/kg) and 24 hours later were randomly assigned to begin daily oral dosing of placebo (n=5) or pioglitazone (5mg/kg; n=5). At baseline, 1 and 12 weeks post-6-OHDA all animals were PET scanned with MHED, PBR28 and ATSM; 24 hours after the final PET scan animals were euthanized by trans-aortic perfusion and heart tissue collected. One week post-neurotoxin, MHED uptake was dramatically reduced in all animals compared to baseline (placebo 86% decrease; pioglitazone 82%). Concurrently, PBR28 uptake was attenuated in the pioglitazone-treated animals compared to placebo (ANOVA $p=0.007$), with the difference most pronounced in the base of the heart. Preliminary analysis of ATSM data also suggests decreased uptake at one week in pioglitazone-treated animals. By twelve weeks post-neurotoxin, partial recovery of MHED uptake was significantly greater in the pioglitazone (54% Retention Deficit (%RD)) animals compared to placebo (70 %RD; ANOVA $p<0.05$), with greatest preservation in the apical, septal left ventricle, while PBR28 and ATSM uptake values returned to baseline levels. Ongoing immunohistochemical quantification of panneuronal marker PGP9.5 and catecholaminergic marker tyrosine hydroxylase (TH) in left ventricle tissue supports PET findings, suggesting preservation of sympathetic nerves in the heart induced by pioglitazone. Overall, these results demonstrate PPARγ-activation induced cardiac sympathetic neuroprotection in association with decreased inflammation and oxidative stress.

Abstract: Patients with Parkinson's disease (PD) are known to have considerable voice and speech impairments that begin to manifest early in the disease progression. The common marmoset (*Callithrix jacchus*) is a target species for PD model development. These New World monkeys are ideal for evaluating vocalizations, as they are social animals who generate a variety of call types without complex elicitation protocols. The purpose of this project is to establish how common marmoset vocalizations change with development in order to understand how and when communication might change in a common marmoset model of PD. Fourteen developing marmosets were longitudinally video- and audio-recorded between the ages of 1-149 days in a naturalistic setting without any vocalization elicitation protocol. Vocalizations were coded for call type (cry, tsik, trill, phee, and trill-phee) and analyzed for duration (sec), minimum and maximum frequency (Hz), and bandwidth (Hz). Mixed model linear regressions were performed to assess the effects of age on call parameters listed above. Tsik bandwidth decreased with age ($p=0.004$) while tsik minimum and maximum frequency increased ($p=0.01$; $p=0.012$). Phee and trill-phee bandwidth also decreased with age ($p=0.04$; $p=0.01$). Call duration did not change with age ($p\geq0.05$). Common marmoset vocalization development is call type-dependent, with tsik, phee, and trill-phee calls changing most with age. Decreases in call bandwidth may represent an improvement in motor control for producing complex calls. This dataset can serve as a comparison group for future studies involving transgenic models of neurological diseases, with the capability for investigation into early changes to vocal function associated with PD pathology and into voice and speech treatment modalities.

Title: Wirelessly programmable module for custom deep brain stimulation

Authors: *E. M. LEWIS[1], C. KEMERE[2];
[2]Electrical and Computer Engin., [1]Rice Univ., Houston, TX

Abstract: Typical experiments in rodent models of Parkinson's disease rely on a tether to deliver deep brain stimulation (DBS) to the implanted electrode. Tethered studies make long-term stimulation and complex behavior study difficult or impossible. While tether-free rodent-scale pulse generators were developed to address this need, they lack the flexibility required to easily test different patterns of stimulation. We developed a wirelessly programmable stimulator and a customizable 3-D printed housing that allow for chronic delivery of normal or novel patterns of DBS in rats. The housing weighs 16.5 g and is: 35 x 26 x 34 mm (l, w, h). The stimulator utilizes an embedded microcontroller to generate biphasic current pulses to a concentric electrode in the subthalamic nucleus. The amplitude of stimulation ranges from 30 to 110 μA, at a frequency of 50 to 200 Hz with a pulse width from 30 to 90 μs. As an additional feature, we are adding the ability to optionally introduce a random offset to the inter-pulse interval. We have previously shown that such jitter, which can vary from 1 to 4 μs, may have therapeutic benefit. These programming settings can be changed wirelessly through near field communication (NFC) with an Android mobile application. We tested our device in vivo in hemiparkinsonian rats (unilaterally-lesioned using injections of 6-OHDA), assessing rotational behavior following amphetamine administration. We found similar behavioral responses to stimulation using a traditional tethered stimulator and our untethered unit. The results of this approach provide a cost effective method for future high throughput studies in rodent DBS. Thus, we anticipate that our open source platform will provide tremendous value to our experiments and to future studies involving chronic stimulation in rodent disease models.

Title: Toward an electrophysiologically defined “sweet spot” for deep brain stimulation within the subthalamic nucleus

Authors: *A. HORN[1], W.-J. NEUMANN[1], K. DEGEN[1], G.-H. SCHNEIDER[2], A. KÜHN[1]; [1]Neurol. Dept., [2]Neurosurg. Dept., Charité – Univ. Med., Berlin, Germany

Abstract: Background: Deep brain stimulation (DBS) of the subthalamic nucleus (STN) in patients with Parkinson‘s disease (PD) is a well established therapy with excellent clinical results. A potential physiomarker of motor symptoms in PD is enhanced power of local field potential (LFP) activity in the beta band[1] and its spatial source could potentially be used to refine DBS targeting. The aim of this study was to map the distribution of beta power from a large cohort of patients onto anatomical space.
Methods: In total, 62 patients
(42 male; mean age 61 ± 9 yrs) that underwent DBS surgery for severe Parkinson's disease (PD) between 2000-2014 were included. Patients received two quadripolar electrodes (Medtronic 3389). Pre- and postoperative MRI were normalized into standard space using DARTEL. Electrode placement was localized using Lead-DBS[2]. LFP recordings were acquired at rest after overnight withdrawal of dopaminergic medication within a postoperative interval of 2-7 days from externalized leads. Power in alpha (8-12 Hz) and beta (13-35 Hz) frequency bands were calculated between adjacent contacts.
Results: Analysis of electrode localizations located 364 of 432 electrode contacts (84%) inside the STN defined by the Morel atlas[3] (Fig. 1A). The peak of the final beta-mapping resided within the postero-dorso-lateral portion of the STN at x = ±12.0 y = -14.4 z = -8.6 mm whereas the alpha-peak was located antero-ventro-medial to it at x = ±11.5, y = -12.5, z = -7.9 mm (Fig 1 B). Our findings suggest a spatial distribution of alpha and beta sources within the STN, the latter highly corresponding to its sensorimotor functional zone.

Title: Three-dimensional definition of two prominent deep brain stimulation targets based on a multimodal high-definition MNI template

Authors: *S. EWERT[1], A. HORN[1,2];
[1]Neurol. Department, Movement Disorders Section, KFO 247, Charité – Univ. Medicine, (berlin, Germany), Berlin, Germany; [2]Dept. of Neurol., Berenson-Allen Ctr. for Noninvasive Brain Stimulation, Beth Israel Deaconess Medical Center, Harvard Medi, MA

Abstract: Background: Deep brain stimulation (DBS) of target structures in patients with Parkinson‘s disease and Dystonia is a well-established therapy. To further optimize this therapy, an evaluation of electrode placement relative to their target structure is essential. To do so, accurate volumetric atlases defining the exact locations of DBS targets in a standardized stereotactic space are needed. Here, we present an atlas that precisely defines the primary two DBS targets, the subthalamic nucleus (STN) and the internal part of the pallidum (GPi) within MNI space.
Methods: An observer independent three-level algorithm was designed to robustly segment subcortical DBS target structures (GPe, GPi, Red nucleus (RN) and STN) within MNI space by simultaneously using T1, T2, proton density and T2 relaxometry versions of the ICBM 152 2009 nonlinear asymmetric template. This algorithm uses intensity values of all four modalities of each brain voxel to calculate Mahalanobis distances from priorly estimated intensity distributions of each target region. Thus, each voxel is assigned a probability to belong to each target structure based on its intensity distribution across acquisitions. Automated results were used as primary guidance to manually segment structures on a high definition version of the template following a manual segmentation protocol for subcortical structures modified from 1.
Results: The algorithm was able to robustly segment all target structures but could not differentiate GPe from GPi. The pallidum was further segmented into GPi and GPe manually. Likewise, STN and RN were re-segmented, resulting in an atlas that gives the exact location of DBS target structures within MNI space (Fig. 1). The atlas will be made available within Lead-DBS software and makes it possible to assess relationships between DBS electrodes and target structures within standard space.

Tourette Syndrome Association (TSA)

Title: Basal ganglia disinhibition in Tourette syndrome

Authors: ***I. BAR-GAD**, M. ISRAELASHVILI;
Bar-Ilan Univ., Ramat-Gan, Israel

Abstract: Tourette syndrome (TS) has been associated with abnormalities in the cortico-basal ganglia (CBG) system, and specifically with abnormal inhibition within the striatum. Functional models of the basal ganglia (BG) emphasize the role of disinhibition of its output nucleus, the

globus pallidus internus - GPi, with the formation of different hyperkinetic disorders including TS. According to these models, global reduction of GPi activity leads to disinhibition of its thalamocortical targets resulting in cortical over-activation and the expression of hyperkinetic symptoms. Focal reduction of GPi activity, on the other hand, leads to disinhibition of local cortical networks and the release of individual movements i.e., tics. In this study we test the disinhibition hypothesis of TS by examining its neurophysiogical correlates in TS patient undergoing implantation of deep brain stimulation (DBS) electrodes and in the rodent and non-human primate (NHP) striatal disinhibition models of the disorder. We recorded the neuronal activity in: (1) Awake TS patients undergoing DBS electrode implantation in the anterior (limbic) GPi. (2) Freely behaving rodents and head restrained NHPs expressing motor tics following local micro-injection of bicuculline, a $GABA_A$ antagonist, into the sensorimotor striatum. The neuronal activity throughout the CBG pathway (globus pallidus in human patients, motor cortex, striatum & globus pallidus in the model animals) was recorded and correlated with the expression of tics. Neuronal activity in the animal models was characterized by tic related neuronal activity which encoded both the location of the tic (via striatal activity) and the timing of the tic (via cortico-striatal input). Activity in both segments of the globus pallidus of TS patients and the animal models was reduced compared to normal controls, presumably due to simultaneous increased inhibition through the direct and indirect pathways. This reduced activity leads to disinhibition of downstream targets of the BG such as the thalamus and cortex. Thus, converging evidence from TS patients and animal models of the disorder demonstrate major changes in the activity of the CBG pathway. These changes which including global and local disinhibition of BG targets are associated with both the overall state of the disorder and the expression of individual tics.

Title: Patient-specific models of local field potentials recorded from deep brain stimulation electrodes

Authors: N. MALING[1], S. F. LEMPKA[2], Z. BLUMENFELD[3], H. BRONTE-STEWART[3], *C. C. MCINTYRE[1];

Abstract: Emerging technological innovations in clinical deep brain stimulation (DBS) are enabling chronic recording of local field potentials (LFPs) from the implanted electrodes, with hopes that the signals could be useful as representative biomarkers of the patient-specific disease state. However, scientific details on the biophysical origin of these LFP signals remains elusive, and little is known about how the patient's unique brain anatomy and electrode placement impact the recording of such signals. Therefore, we developed a computational framework to theoretically analyze LFP recordings from clinical DBS electrodes that can be customized to individual patients. To demonstrate our model system, we selected a subject with Parkinson's disease implanted with a Medtronic Activa PC+S DBS system. A patient-specific reconstruction of their subthalamic nucleus (STN) and DBS electrode implant location was generated using their clinical imaging data (MRI and CT). This patient-specific anatomical model was then used to define the parameters of a finite element volume conductor model, and to dictate the locations of 200,000 STN multi-compartment cable model current sources relative to the implanted DBS electrode in an anatomically realistic way. We then used this model system to examine the impact of distributing subpopulations of highly synchronous neurons within the STN volume on the recorded LFP signal and compared those theoretical results to the experimentally measured LFPs. We found that incorporating patient-specific STN anatomy resulted in measureable changes to LFP amplitude compared to a spherical STN shape. We also found that the recording configuration and filtering effects have a substantial impact on the amplitude and frequency content of the recorded signal. Neuronal density in the area surrounding the electrode had a graded effect on LFP amplitude, while a more profound effect was generated by varying the synchrony of spatially discrete subpopulations of neurons near the electrode. Finally, we found that explicitly incorporating patient-specific details into appropriately parameterized DBS LFP models enabled us to accurately reproduce key features of the experimentally recorded signals, such as state-dependent modulation and recording location dependence of beta band activity.

Title: Subthalamic nucleus oscillations as predictor of motor cortical excitability measured by transcranial magnetic stimulation

Authors: *K. UDUPA[1,2], A. GHAHREMANI[3], J. R. WESSEL[4], U. SAHA[2], T. HOQUE[2], A. R. ARON[5], R. CHEN[3];
[1]Krembil Res. Institute, UHN, Toronto, ON, Canada; [3]Neurology/Medicine, [2]Krembil Res. Inst., Toronto, ON, Canada; [4]Dept. of Psychological and Brain Sci., Univ. of Iowa, Iowa city, IA; [5]Dept. of Psychology, Univ. of California San Diego, La Jolla, CA

Abstract: It is well known that there is considerable trial-to-trial variation in motor evoked potential (MEP) amplitudes evoked by transcranial magnetic stimulation (TMS) of the motor cortex (M1), but the basis of this variability is not well understood. Electroencephalographic (EEG) studies have shown that higher MEP amplitudes are associated with decreased beta power in the rolandic regions and increased fronto-parietal beta band coherence about one second prior to the stimulation. Since cortical oscillations are strongly influenced by subcortical (basal ganglia-thalamocortical) networks, fluctuations in subthalamic nucleus (STN) local field potentials (LFP) could also relate to this variability. We hypothesized that higher MEP amplitudes (more motor excitability) would be associated with lower beta band power in the STN (less of an 'akinetic' signature). We studied 11 Parkinson's disease patients implanted with STN deep brain stimulation electrodes with externalized leads. Using TMS, we stimulated the left M1 (70mm, figure of eight coil, 20 trials with 5 sec between trials) to elicit 1mV MEP amplitude in the resting right first dorsal interosseous muscle. We recorded LFP oscillations in bilateral STN from deep brain stimulation electrodes and computed the LFP power before TMS (-200 to -1000 ms) in the theta (4-8 Hz), alpha (8-12 Hz) and beta (12-30Hz) frequency ranges using bipolar montages (0-1, 1-2, 2-3). MEP amplitudes from individual trials had significant positive correlation with beta power in the left STN in seven out of 11 patients, whereas no correlation was found for the right STN. Fluctuations in theta and alpha power did not correlate with MEP amplitudes. The average MEP (20 trials) amplitude also positively correlated with amplitude of beta oscillations in left STN across patients ($r=0.58$, $p=0.04$). Our study demonstrates that spontaneous variations in STN beta oscillations may predict cortical excitability as measured by MEP amplitudes in Parkinson's disease patients. However, we found that higher MEPs were related to increased STN beta (rather than decreased STN beta as per our hypothesis). This could be due to coupling of STN beta to M1-gamma oscillations, which could influence motor cortical excitability.

Title: Modulation of subthalamic γ oscillations by movement parameters in Parkinson‘s disease

Authors: *R. LOFREDI[1], A. BOCK[1], W.-J. NEUMANN[1], J. HÜBL[1], S. SIEGERT[1], G.-H. SCHNEIDER[1], J. KRAUSS[2], A. KÜHN[1];
[1]Neurol., Klinik Für Neurologie - Charité Campus Virchow-Kli, Berlin, Germany; [2]Klinik für Neurochirurgie, Medizinische Hochschule Hannover, Berlin, Germany

Abstract: Question: Parkinson‘s disease (PD) is a common medical condition leading to slowness of movement. Recently, pathologically enhanced synchronized oscillations in the basal ganglia have been proposed as a pathophysiological hallmark of PD. Specifically, enhanced synchronization in the β band (13-30 Hz) has been associated with bradykinesia and rigidity in PD. Synchronization in the γ band (40-90 Hz) and of high frequency oscillations (HFO, >100 Hz) are more prominent ON medication in PD and considered prokinetic. Pallidal γ band oscillations have been shown correlated to movement amplitude and velocity. Here we investigated if γ oscillations in the human subthalamic nucleus (STN) are related to scaling of movement.
Methods: 16 PD patients (4 female, mean age 58.4 years +/-2.8 SEM) undergoing deep brain stimulation in the STN were included in the study. Bipolar local field potentials from 3 adjacent contact pairs were recorded while patients were on their usual dopaminergic medication. Patients performed forearm pronation movements of three amplitudes (‘small’, ‘medium’, ‘large’). Signals were taken into the frequency domain using wavelet analysis, averaged and normalized to a pre-trial baseline period. Normalized time frequency plots were averaged across hemispheres and patients. Statistical analysis was conducted using non-parametric Wilcoxon-sign rank tests. Averaged β (13-30 Hz), γ (40-90 Hz) and HFO (100-400 Hz) were compared across hemispheres, movement amplitude and velocity and correlated with the clinical symptom severity as measured by the UPDRS-III.
Results: Movement aligned analysis revealed a significant desynchronization in the β band and an increase of synchronization in the γ and HFO band ($p<.05$, FDR corrected) of the STN. Movement-related contralateral γ synchronization was modulated by movement amplitude with highest γ power in the ‘large’ movement condition within patients. Furthermore, increase of contralateral γ power correlated with averaged movement velocity (Spearman’s Rho=0.55, $p=0.018$) across all patients. Finally, mean power of contralateral γ oscillations correlated

negatively with UPDRS III (Spearman's Rho =-0.6, p=0.014).
Conclusions: Here we show that synchronization of subthalamic γ oscillations are related to movement velocity and amplitude in the ON medication condition supporting the notion that γ activity is a prokinetic feature in PD. Further analyses should reveal if γ synchronization is impeded by enhanced beta band activity OFF medication leading to slowness of movement.

Title: Cortico-basal ganglia connectivity in non-human primates: Implications for the therapeutic effect of STN stimulation in PD patients.

Authors: *A. MATIS[1], R. N. LEMON[1], D. C. ALEXANDER[2], A. KRASKOV[1];
[1]Sobell department of motor neuroscience and movement disorders, UCL Inst. of Neurol., London, United Kingdom; [2]Dept. of Computer Sci., Ctr. for Med. Image Computing, London, United Kingdom

Abstract: The connection between the basal ganglia and motor cortical areas is important in mediating normal response inhibition and has been proposed to play an important role in the pathology of Parkinson's disease (PD). Therefore, understanding cortico-basal ganglia connectivity and its alterations in disease is essential for understanding PD mechanisms and explaining and improving existing treatments such as deep brain stimulation (DBS). One plausible hypothesis as to how DBS of the subthalamic nucleus (STN) produces its therapeutic effect is by normalizing the activity of motor cortical neurons, which project directly to the STN and are antidromically activated by DBS (Gradinaru et al. 2009; Li et al. 2012). The main research question here is how the STN is connected to motor and other cortical areas across different primate species and how this connectivity changes with pathology and DBS treatment.We use probabilistic tractography to map cortical connections to the STN in four ex-

vivo macaque monkeys (data kindly provided by Evan Calabrese, Duke University, Calabrese et al. 2014) and compare these to results from conventional tracing studies (Haynes & Haber 2013).We found that STN had its strongest connectivity to limbic cortical areas (areas 11, 13, 14, 25, OPro, OPAll) and this connectivity was confined to medio-ventral regions of the STN. This area overlapped extensively with parts of the STN connected to cognitive cortical areas (areas 8-10, 44-46). We confirmed that the dorso-lateral part of the STN had its strongest connectivity to motor cortical areas (M1, SMA, PM) and fibers are likely to enter the STN from its dorso-lateral pole. These results speak in favour of two subdivisions of the STN: a lateral region connected to motor areas and a medio-ventral region to limbic and cognitive cortical areas.We further found that M1 input into STN was restricted to the dorso-lateral pole of STN whereas input from SMA was located more ventro-medial which is in line with tracing studies (Nambu et al.1996). The largest motor input to STN came from caudal dorsal premotor cortex (PMdc, 73.20 ± 54.44 out of 5000 streamlines) and rostral ventral premotor cortex (PMvr, 28.03 ± 8.77 out of 5000 streamlines) and was located medial to M1 input.To establish a connection between the activation of motor cortical neurons by STN DBS and its therapeutic effects in patients with PD, it is essential to understand the connectivity of the STN to these areas and the identity of these cortical neurons. This will have implications on the optimal location of DBS for specific motor deficits in PD patients and reduction of unwanted side effects.

Title: Phosphodiesterase 9 inhibition therapy for Parkinson’s disease

Authors: ***S. M. PAPA**[1], A. SINGH[2], G. MASILAMONI[2], X. TANG[2], L. LEVENTHAL[3]; [1]Neurol., Emory Univ., Atlanta, GA; [2]Yerkes Natl. Primate Res. Center, Emory Univ., Atlanta, GA; [3]FORUM Pharmaceuticals, Inc., Waltham, MA

Abstract: Striatal phosphodiesterases regulate selectively the cyclic nucleotides cAMP and/or cGMP that are involved in signaling pathways modulated by dopamine. Depending on the

isoenzyme substrate, selective inhibitors may impact differently L-dopa effects in Parkinson's disease (PD). Phosphodiesterase 9 (PDE9) regulates cGMP but not cAMP, thereby influencing particular dopamine receptor mechanisms in striatal projection neurons. In this study, we determined the effects of a selective PDE9 inhibitor in monotherapy and co-administration with L-dopa in the non-human primate (NHP) model of PD. Six macaques (*Macaca fascicularis*) were rendered severely parkinsonian by repeated MPTP administration, and maintained under regular treatment with L-dopa/carbidopa (Sinemet 100/25 mg). PDE9 inhibitor doses from 0.12 to 7.5 mg/kg (s.c.) were tested alone or in combination with either of two doses of L-dopa methyl ester plus benserazide (threshold and suboptimal doses). Standardized scales were used for blinded assessment of motor disability, levodopa-induced dyskinesias (LID), and other neurologic effects. Pharmacokinetics (PK) of the PDE9 inhibitor and L-dopa were studied and correlated with behavioral results. The PDE9 inhibitor (2.5 and 5 mg/kg) significantly potentiated the antiparkinsonian effect of L-dopa on acute tests in NHP. Motor disability scores were lower throughout the entire L-dopa response ($p < 0.01$), which was also longer demonstrating a clear prolongation of the "on" state ($p < 0.01$). PDE9 inhibition had significant effects on both threshold and suboptimal L-dopa responses. No direct PDE inhibitor effects on LID were observed. This agent had no significant motor effects on monotherapy. In all tests of the PDE9 inhibitor, no significant adverse reactions were observed. These results suggest that PDE9 inhibition may be a therapeutic strategy to extend and smooth responses to L-dopa facilitating the use of lower doses that also reduce abnormal motor responses.

Title: Striatal overexpression of ΔFosB leads to the development of dyskinesias in parkinsonian non-human primates without chronic levodopa exposure

Authors: *A. SINGH[1], L. F. POTTS[1], M. MARTINEZ[1], J. M. YOO[2], E. S. PARK[2], J. ZHANG[2], E. JUNN[2], M. M. MOURADIAN[2], S. M. PAPA[1,3];

Rutgers-Robert Wood Johnson Med. Sch., Ctr. for Neurodegenerative and Neuroimmunologic Dis., Piscataway, NJ; [3]Dept. of Neurol., Emory Univ. Sch. of Med., Atlanta, GA

Abstract: The transcription factor ΔFosB has been involved in the pathogenesis of levodopa-induced dyskinesias (LID) due to the observed increase in its striatal expression in animal models and Parkinson's disease patients exposed to chronic levodopa treatment. However, the levels of striatal ΔFosB are already elevated after dopamine depletion, and the role of this transcription factor in the mechanisms of altered responses to levodopa is unclear. We studied the effect of striatal ΔFosB overexpression induced by a viral vector in parkinsonian non-human primates that were maintained naïve of levodopa treatment. rAAV-ΔFosB or GFP was infused in the putamen and caudate bilaterally in 8 cynomolgus monkeys with moderate-severe parkinsonism. The response to a levodopa (s.c.) dose was determined before the virus infusion as baseline, and 4 weeks after virus infusion the response to the same levodopa dose was tested weekly for 3 months. Animals did not receive daily levodopa treatment. In 4 animals, recording chambers were surgically implanted for single cell recordings to analyze the striatal projection neuron (SPN) activity during the weekly responses to levodopa. At the end of the study, the expression of ΔFosB or GFP in the striatum was determined in all animals. We found that the transgenic ΔFosB overexpression in the striatum caused rapid development of LID in all animals, and in some as early as in the first levodopa test post-AAV infusion. These results contrasted with the lack of LID in the animals receiving the control virus (rAAV-GFP), that were also tested with weekly levodopa injections just as were tested the rAAV-ΔFosB-infused animals. The electrophysiology data showed predominance of inversion of SPN firing frequency changes (bidirectional changes) during the response to levodopa, which characterizes the altered dopamine responses associated with the expression of LID. The increase in bidirectional responses correlated with the AAV-ΔFosB infusion and the appearance of LID. Conversely, a higher proportion of unidirectional responses were associated with the absence of LID in animals infused with the control virus. Immunoblotting analysis of protein extracts from striatal tissue obtained at the end of the study demonstrated consistent overexpression of ΔFosB (or GFP) across animals. These results demonstrate that the high striatal ΔFosB expression, independent of levodopa exposure, can lead to dyskinetic responses to levodopa, supporting a causal role of ΔFosB in LID development.

Abstract: The caudal intralaminar thalamic nuclei, i.e., the centromedian and parafascicular nucleus (CM/PF), provide massive thalamic input to the striatum, targeting spiny projection neurons and interneurons. Although CM/PF inputs are glutamatergic, we found previously (Nanda et al 2009) that electrical stimulation of the CM/PF evokes combinations of increases and decreases in firing in striatal neurons. To further investigate this issue, we studied the effects of selectively activating the terminals of the CM/PF-striatum connection, using an optogenetic approach.

Two monkeys received recording chambers for access to CM/PF and the caudate/putamen. We injected AAV5-hSyn-ChR2-EYFP or AAV5-hSyn-C1V1-EYFP in the CM/PF complex. Six 6 weeks later, we introduced optrodes (tungsten electrodes glued to 0.2 mm OD optical fibers) into the putamen or the caudate nucleus and activated opsin-positive terminals of the CM/PF-striatal projections with light pulses (>200 mW/mm2; single pulses, 500 ms duration), while recording the electrical activity of striatal neurons with standard extracellular recording methods.

We recorded the activity of 41 neurons in the caudate and 487 neurons in the putamen from the 2 monkeys. Approximately 40% of caudate and 20% of putamen neurons responded with significant decreases in firing during the light stimulation, while less than 10% of neurons showed increases in firing. The decreases in firing started, on average, 150 ms after the start of the light pulse, although some neurons responded with much shorter (< 10 ms) responses. Projection or interneurons (distinction based on unstimulated firing rates) responded to stimulation. The predominance of inhibitory effects of the optical activation of CM/PF terminals and the long latency of the striatal responses suggests that many of the effects were not monosynaptic, but that the transfected CM/PF terminals in the striatum exerted their effects by activating intrastriatal or other inhibitory pathways. Presumably, similar networks would also be engaged by the glutamatergic CM/PF inputs under physiologic conditions. We will conduct postmortem analyses of the brain tissue of these animals to study the distribution of the opsin-expressing CM/PF terminals in the striatum, as well as their cellular targets.

Abstract: Introduction Cortico-basal ganglia circuit model, or firing rate model, successfully link striatal dopamine depletion and bradykinesia in Parkinson's disease (PD). However, the model provokes several conflicts with clinical observations. For example, the model is difficult to reconcile with the fact that lesions in the motor thalamus were found to relieves symptoms, rather than worsen bradykinesia in PD patients. **Methods** Seventeen PD patients and 16 healthy control subjects (HC) underwent [^{11}C]-CFT PET. Whole brain BOLD fMRI during hand movement and rest, T1 weighted image and field map data were also acquired with a 3T scanner. Analyses were performed using FMRIB Software Library (FSL) v5.0.7 tools. First, we set regions of interest (ROIs) on striatal area showing significant ^{11}C-CFT binding reduction in PD compared to HC. Then, we examined functional connectivity of the ROIs in PD and HC. **Results** The striatal ROIs demonstrated functional connectivity with the cortical motor areas, thalamus, internal gllobus pallidum (GPi) and substantia nigra (SN), in both PD and HC, though the strength of functional connectivity was decreased in PD compared with HC. In contrast, the strength of functional connectivity of the ROIs with the striatum, thalamus and subthalamic nucleus (STN) linearly increased in patients with severe bradykinesia, implicating a connection between the abnormal subcortical network and bradykinesia in PD. Meanwhile, the strength of functional connectivity of another network including the striatum, thalamus, and cerebellum correlated with the degree of tremor. **Discussion** Based on the present findings, we propose that striatal dopamine depletion decreased functional connectivity with the cortical motor areas, thalamus, GPi, and SN in PD. We also propose that emergence of abnormal functional network underlay motor symptoms in PD: increased functional connectivity among the striatum, thalamus and STN was associated with bradykinesia whereas enhanced connectivity among the striatum, thalamus and cerebellum was related to tremor.

Title: Morphological evidence supporting dopamine D1/D2 receptor heteromers in the striatum of the long-tailed macaque. Changes following dopaminergic manipulation.

Abstract: Although it has long been widely accepted that dopamine receptors types D1 and D2 form GPCR heteromers in the striatum, the presence of D1/D2 receptor heteromers in the adult mammalian brain has been recently challenged. In an attempt to properly characterize the presence/absence of D1/D2 receptor heteromers, here we have used the *in situ* proximity ligation assay (PLA) in striatal sections comprising the caudate nucleus, the putamen and the core and shell territories of the nucleus accumbens. Experiments were carried out in control macaques as well as in MPTP-treated animals (with and without dyskinesia). Obtained data support the presence of D1/D2 receptor heteromers within all the striatal subdivisions, with the highest abundance in the accumbens shell. Dopamine depletion by MPTP resulted in an increase of D1/D2 density in caudate and putamen which was normalized by levodopa treatment. Two different sizes of heteromers were consistently found, thus suggesting that besides individual heteromers, D1/D2 receptor heteromers are sometimes organized in macromolecular complexes made of a number of D1/D2 heteromers. Furthermore, the PLA technique was combined with

different neuronal markers to properly characterize the identities of striatal neurons expressing D1/D2 heteromers. We have found that striatal projection neurons giving rise to either the direct or the indirect basal ganglia pathways expressed D1/D2 heteromers. Interestingly, macromolecular complexes of D1/D2 heteromers were only found within cholinergic interneurons. In summary, here we provide overwhelming morphological proof that D1 and D2 receptors form heteromeric complexes in the macaque striatum, thus representing a very appealing target for a number of brain diseases involving dopamine dysfunction

Title: Early loss of extra-striatal dopaminergic innervation in a progressive MPTP monkey model: a putative compensatory mechanism?

Authors: *I. TRIGO DAMAS[1], A. VIAN-LAINS[2], H. IWAMURO[3], J. BLESA[1], M. SANCHEZ-GONZALEZ[2], C. CAVADA[2], J. OBESO[1];

Abstract: Traditionally, the major pathophysiological emphasis in Parkinson's Disease (PD) has resided in striatal dopamine (DA) deficit. However, the *substantia nigra pars compacta* (SNc) has projections to other basal ganglia (BG) nuclei; and the thalamus, brainstem and cortex are also innervated by DA axons. Earlier reports have also shown that DA loss in the subthalamic nucleus (STN) is already present at the onset of motor symtoms in both PD patients and in the 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) monkey model of parkinsonism. Such DA loss in the STN would precede DA reduction in the external and internal segments of the globus pallidus (GPe/GPi). However, it is unclear how early in the evolution of pakinsonism extra-striatal DA depletion occurs. Moreover, the physiological effects of DA differ in the various BG nuclei. In order to examine the DA depletion in the extra-striatal BG nuclei, the length of DA axons was measured in the STN and GPe/GPi of 20 monkeys: a control group and MPTP-treated groups classified, according to their motor state, in asymptomatic, recovered and parkinsonian. The total length of axons immunoreactive for the DA transporter was estimated employing a hemispherical probe combined with unbiased fractionator sampling using StereoInvestigator® software (MicroBrightField Bioscience, Williston, VT, USA). The results show a decrease of ≈ 40% of axonal length and density in STN at early stages of nigro-striatal DA depletion, i.e. in the asymptomatic monkeys. The decrease is maintained through the progressive motor-impaired states. Moreover, we have examined the effects of Quinpirole (DA agonist) and Sulpiride (DA antagonist) microinjections within the STN and GPe in the motor behavior of parkinsonian monkeys. Briefly, the DA agonist in STN led to motor aggravation whereas the antagonist provoked modest improvement. Moreover, microinjections of the DA agonist in GPe, even if not so clear, also result in motor worsening of the animal, who also presented abnormal movements. We propose that DA denervation in the STN takes place early in the evolution of nigro-striatal degeneration and it may play an important compensatory role in the pre-symptomatic stage of PD. Accordingly, an early reduction of DA input would decrease neuronal excitability and delay the onset of abnormal firing patterns in the STN and other extra-striatal nuclei. This in turn would keep BG output within normal limits, thus delaying the onset of motor symptoms in PD.

Abstract: The striatum harbors a population of neurons that express tyrosine hydroxylase (TH), an enzyme necessary for dopamine (DA) synthesis and a useful marker for DA neurons. The number of striatal TH-positive neurons (TH+) increases markedly in animal models of Parkinson's disease (PD). In humans, the presence and significance of TH+ neurons in the striatum of PD patients has been controversial. Likewise, the effect of L-dopa treatment and of DA striatal concentrations on the number of these neurons is unclear. Despite being relatively few in number, the TH+ neurons could be a local source of DA and thus, they may play a role in transmitting and distributing neuromodulatory signals in the DA denervated striatum of parkinsonism. The TH+ striatal neurons may act as a compensatory mechanism apt to be enhanced to alleviate or delay the clinical onset of PD. Therefore, it is crucial to understand well the population of TH+ neurons in order to comprehend more fully its pathophysiological role and its therapeutic potential. We have investigated the phenotype and fate of TH+ striatal neurons in non-human primates rendered parkinsonian by MPTP intoxication and in PD patients. Four control monkeys and 18 MPTP-intoxicated monkeys were studied. The latter included monkeys who were always asymptomatic, monkeys who recovered after showing mild parkinsonian signs, monkeys with stable parkinsonism, either moderate or severe, and L-Dopa treated parkinsonian

monkeys. Thus, unlike previous studies, we analyzed striatal TH+ neurons at different stages of the parkinsonian condition. Our results show that the numbers of TH+ neurons increase very early in the evolution of the nigro-striatal DA deficit, including the stage when no motor symptoms are present. They increase even further as the condition progresses to severe parkinsonism but their increment was completely abolished when parkinsonian monkeys were treated with L-Dopa. Similarly, PD patients examined in this study were also treated with L-Dopa to compensate for the loss of striatal DA. Accordingly, the striatum of PD patients was found to contain less TH+ neurons than that of controls. These data support the hypothesis that TH+ striatal neurons could serve as a compensatory mechanism for restoring striatal DA levels in the pre-symptomatic stages of experimental parkinsonism and of PD.

Title: Dopamine and serotonin hyperinnervation of the globus pallidus in parkinsonian monkeys

Authors: *D. GAGNON[1], L. EID[1], C. WHISSEL[1], A. BRAUN[1], T. DI PAOLO[2], M. PARENT[1];
[1]CR-IUSMQ, Quebec, QC, Canada; [2]CR-CHUQ, Quebec, QC, Canada

Abstract: The primate pallidum is divided into an internal (GPi) and an external (GPe) segment, both receiving a highly heterogeneous serotonin (5-HT) and dopamine (DA) innervation. The main purpose of this light and electron microscopic study was to characterize neuroadaptive changes of 5-HT and DA axons in the GPi and GPe of a non-human primate model of Parkinson’s disease (PD). Eight cynomolgus monkeys (*Macaca fascicularis*) were used: 4 were rendered parkinsonian by systemic injections of MPTP and 4 served as controls. The state of 5-HT and DA pallidal innervation was evaluated by means of immunohistochemistry with antibody raised against the 5-HT transporter (SERT) and tyrosine hydroxylase (TH). The densities of immunolabeled axons and axon varicosities were estimated using an unbiased stereological approach. Overall, the GPi of macaque monkeys is more densely innervated by 5-HT than the GPe ($0.43 \pm 0.05 \times 10^6$ SERT+ axon varicosities/mm^3 vs. 0.32 ± 0.03). Intoxication

with MPTP induces a two-fold increase in the density of SERT+ axon varicosities in both pallidal segments ($0.75 \pm 0.07 \times 10^6$ SERT+ axon varicosities/mm^3 in the GPi and 0.61 ± 0.05 in the GPe). This change is accompanied by an increase in SERT+ axonal length in the pallidum. Ultrastructural features and synaptic incidence of SERT+ axon varicosities are similar between MPTP and control monkeys, in both pallidal segments. Our preliminary results of TH innervation indicate that the primate pallidum is less densely innervated by DA than by 5-HT axons with $0.18 \pm 0.09 \times 10^6$ TH+ axon varicosities/mm^3 in the GPi and 0.14 ± 0.01 in the GPe. A significant increase of the TH pallidal innervation is noted following MPTP administration, and this augmentation is more pronounced in the GPi with $0.59 \pm 0.10 \times 10^6$ TH+ axon varicosities/mm^3. An increase in TH+ axonal length is also noted in the GPi of MPTP monkeys. In contrast to the GPi, the GPe of parkinsonian monkeys shows a significant numerical decrease of the large and non-varicose TH+ axons. Altogether, our data reveal that both the DA and the 5-HT neuronal systems that innervate the primate pallidum are highly plastic and able to reorganize themselves in a significant manner in MPTP-intoxicated monkeys. In contrast to the massive degeneration of the nigrostriatal DA system that characterizes the PD state, the DA projection to the GPi, the major output structure of the basal ganglia, appears to be preserved and even increased in PD monkeys. We hypothesize that, based on their remarkable resistance and flexibility in face of a major neurotoxic insult, the DA and 5-HT pallidal inputs play a significant role in the expression of motor and non-motor symptoms of PD and of L-Dopa-induced dyskinesia.

Abstract: Objective: It is suggested that exercise may improve motor function in Parkinson's disease (PD) through increased dopamine (DA) release. The purpose of this study was to investigate differences in DA release induced by exercise or repetitive transcranial magnetic stimulation (rTMS) in participants with PD.
Methods: 28 PD participants were allocated into habitual exercisers (n=8) or sedentary (n=20) based on self-reported exercise frequency and verified by maximal oxygen consumption (VO_2 max). To examine DA release, participants underwent two [^{11}C]Raclopride (RAC) PET scans separated by either (a) 30min of cycling at a target intensity of 60% VO_2 reserve (0.6 x (VO_2 max - VO_2 rest) + VO_2 rest) (habitual n=8, sedentary n=9), or (b) rTMS over the primary motor cortex of the least affected hemisphere (sedentary n=11). Change in binding potential (ΔBP) (post stimulation - baseline scan=DA release) was examined in 8 regions of interest (ROIs) in the caudate and putamen. A texture and shape analysis will also be conducted to determine the change in spatial distribution of RAC.
Results: A group by hemisphere interaction ($F_{(2, 23)}$=8.31, p<.01) for ΔBP_{ND} was found in caudate. Fisher's LSD post-hoc test revealed the exercise stimulus to have significantly greater DA release in PD habitual exercisers compared to sedentary PD subjects ($p<0.01$ in both hemispheres), as well as compared to rTMS induced DA release ($p<0.01$ in both hemispheres)(fig. 1). There were no differences observed in the putamen in habitual exercisers or sedentary subjects for either stimuli.
Conclusion: These findings suggest that aerobic exercise is a suitable stimulus to elicit DA in caudate of habitual exercisers. Additionally, rTMS did not elicit consistent DA release in sedentary PD subjects. Further analysis on rTMS in habitual exercisers needs to be conducted.

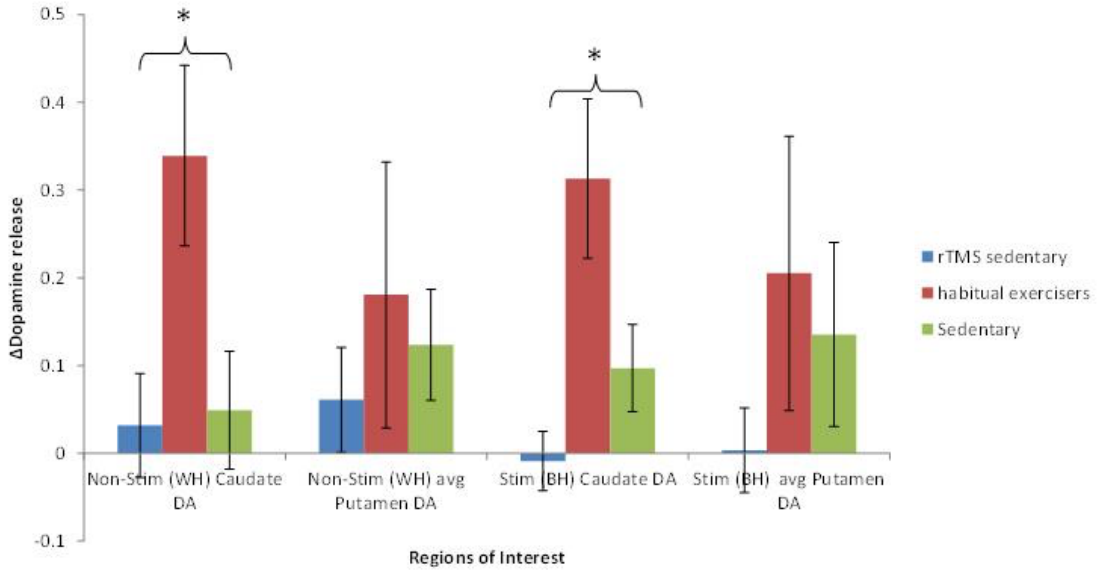

Figure 1. Change in binding potential with [^{11}C]Raclopride in Parkinson's disease subjects who are sedentary or habitual exercisers. Regions of interest (ROIs) include the caudate and average putamen (mean of anterior, middle and posterior ROIs). Δ Dopamine release, baseline binding potential – Post stimulus. Exercise stimulus: 30 minutes of aerobic exercise (cycling on a bicycle at 60 rpm) at 60% of maximal oxygen consumption (VO_2) reserve in PD habitual exercisers and sedentary PD subjects. Repetitive transcranial magnetic stimulation, rTMS: 4x150 stimulations at 90% resting motor threshold at 10Hz, 10 min rest between blocks in sedentary PD subjects. WH, worse hemisphere contralateral to the more affected side of the body (non-stimulated hemisphere); BH, better hemisphere (stimulated hemisphere). Error bars denote standard error of the mean. * $p<0.01$

Title: Plastic resting-state networks in MPTP-treated monkeys

Authors: *J. A. AUTIO[1], N. TANKI[1], T. OSE[1], J. TAKAHASHI[2], T. HAYASHI[1];
[1]Functional Architecture Imaging Unit, RIKEN, Ctr. For Life Sci. Technologies, Kobe, Japan;
[2]Kyoto University, CiRA, Kyoto, Japan

Abstract: Introduction: Synchronized network activity is thought to play a central role in motor coordination, yet their role in pathophysiology of Parkinson Disease remains unclear. Converging electrophysiological and fMRI studies show anomalous synchronizations of cortico-basal ganglia circuits, however, whether these correspond with loss of dopaminergic neurons and Parkinsonian motor symptoms remain inconclusive. Here, we investigated neuronal synchronization in Parkinsonian animal model using fMRI and PET in anesthetized monkeys.
Methods: Study consisted a total of 14 monkeys: 6 were treated with repeated and 2 with a single-dose injection of MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine). MRI experiments were performed using 3 T scanner in combination with a custom-made 16-channel coil. Resting-state scans (TR 760 ms, $1.5 \times 1.5 \times 1.8$ mm^3) comprised 150 minutes per animal. Data was analyzed using temporal function mode (TFM), as described in Smith (2012, PNAS). Animals exposed to a single-dose MPTP injection, dopamine function was repeatedly assessed using dopamine transporter ligand, ^{11}C-PE21, and microPET.
Results: We found 6 TFMs in monkey brain, exhibiting similarity to the ones reported in humans (Smith, 2012). Animals with repeated MPTP-injection showed Parkinsonian motor symptoms and an increase in the sensorimotor TFM ($p < 0.05$, TFCE-corrected), particularly in sensorimotor and premotor areas and striatum as compared with non-MPTP treated animals (N=6). While a single-dose MPTP-injection in the unilateral carotid artery initially induced motor dysfunction and suppressed the binding of dopamine transporter, the sensorimotor TFM increased in the ipsilateral striatum and bilateral sensorimotor area. Strikingly, regardless of persistent ipsilateral dopaminergic loss after 1 month of MPTP injection, normalization of Parkinsonian motor symptoms coincided with network normalization.
Conclusions: Our results show that while partial dopaminergic dysfunction initiates sensorimotor network anomaly, network re-synchronization and behavioral recovery may occur despite persistent impairment of dopaminergic function. These results add additional weight to the idea that large-scale brain synchronization is essential for motor coordination and suggest that Parkinson Disease therapy may benefit from targeting functional network normalization.

Title: Phase amplitude coupling of electrocorticogram signals in a progressive model of primate parkinsonism

Authors: *A. DEVERGNAS[1,2,3], M. CAIOLA[4], D. PITTARD[1,3], T. WICHMANN[1,2,3]; [1]neurosciences, Yerkes Natl. Primate Res. Ctr., Atlanta, GA; [2]Dept. of Neurology, Emory university, Atlanta, GA; [3]Udall Ctr. of Excellence in Parkinson's Dis. Reseach, EMory Univ., Atlanta, GA; [4]Dept. of Mathematical Sci., Rensselaer Polytechnic Institute, NY

Abstract: The degeneration of the nigrostriatal dopaminergic system in Parkinson's disease (PD) triggers pathologic oscillatory patterns in single cell and local field potential activities throughout the entire basal ganglia-thalamocortical network. As part of these changes, recent studies have described that the coupling of the phase of beta band oscillations and the amplitude of gamma band oscillations (50-200 Hz) of electrocorticogram signals from the primary motor cortex (M1) is stronger in PD patients than in patients with craniocervical dystonia or individuals without a movement disorder. The high level of phase-amplitude coupling (PAC) in parkinsonian patients was reduced by therapeutic deep brain stimulation. However, concomitant or past exposure to dopaminergic and other drug therapies may have affected these results. To clarify the relationship between cortical PAC and the motor impairment, we analyzed the relationship between the appearance of motor disabilities and the changes in PAC in electrocorticogram signals from M1 and the supplementary motor area (SMA) in two monkeys that underwent weekly injections of dopaminergic neurotoxin MPTP, rendering them progressively parkinsonian. We also examined the effect of antiparkinsonian levodopa treatment or therapeutic STN high frequency stimulation on cortical PAC in the fully parkinsonian state. We found that the development of parkinsonism was associated with increased coupling between the phase of alpha band oscillations (4-10 Hz) and the amplitude of high gamma band oscillations (50-150 Hz) in M1 and SMA. The changes were not detectable in the mildly parkinsonian state, but reached significance when the animals were more severely impaired. The increased alpha-gamma band PAC was significantly reduced after levodopa treatment or therapeutic STN stimulation. The PAC values were not correlated with the oscillatory power

found in the alpha or high gamma band. These results confirm that abnormal PAC is present in electrocorticogram signals in the advanced parkinsonian state. However, cortical PAC does not seem to be present in more mildly affected animals, suggesting that the PAC may not be essential for the development of parkinsonism, and that it may not be a sensitive biomarker for (early) PD.

Title: GPx4 protects against oxidative stress-induced deficits in mitochondrial import: Implications for Parkinson's Disease

Authors: ***C. W. BARRETT**, P. J. BARRETT, A. D. MORTIMER, C. T. CHU, J. T. GREENAMYRE, T. G. HASTINGS, 15260;
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Parkinson's disease (PD) is the second most common neurodegenerative disease. The hallmarks of PD include oxidative stress and mitochondrial dysfunction, both of which can be reduced with proper mitochondrial antioxidant systems. We have observed that a mitochondrial antioxidant protein is decreased in dopaminergic neurons in PD. The phospholipid hydroperoxide glutathione peroxidase (GPx4) is a potent redox active selenoprotein which is protective against ROS and membrane lipid peroxidation. GPx4 knockout is embryonic lethal and its inducible knockout in adult mice results in neurodegeneration, demonstrating the importance of GPx4 to development and survival. Some of the most essential machinery to mitochondrial health is intricately associated with the inner and outer mitochondrial membranes. For example, the mitochondrial import machinery, pivotal for uptake of 99% of mitochondrial proteins, is dependent on proper incorporation of cardiolipin into the inner mitochondrial membrane and maintenance of membrane potential. Of note, overexpression of mitochondrial GPx4 reverses a mitochondrial import defect in a mouse diabetic heart model suggesting that GPx4 can protect mitochondrial protein import. As GPx4 is pivotal to the protection of the

mitochondrial membrane from lipid peroxidation and is known to interact with cardiolipin, we hypothesized that *GPx4 would protect against oxidative damage-driven deficits in mitochondrial protein import*. In support of this hypothesis, GPx4 knockdown at 42% of endogenous levels in a dopaminergic cell line results in a 77% decrease in import of mitochondrially targeted GFP (N=3, $P<0.01$) and overexpression of mitochondrial GPx4 results in a 63% increase in import into isolated brain mitochondria (N=9, $P<0.05$). Treatment of isolated brain mitochondria with increasing concentrations of the oxidative stressors iron-ascorbate or tertiary-butyl hydroperoxide resulted in significant decreases in import of a radioactive mitochondrially targeted protein, and mitochondria isolated from GPx4 overexpressing mice (GPx4 Tg^{+}) demonstrated rescue of these import deficits. The mechanism for import protection may be due to decreased oxidative damage within the membrane and membrane-associated proteins in response to GPx4 overexpression. Indicative of increased functional import, there is a 3-fold increase in the proximity, assessed by proximity ligation assay, of mitochondrial import proteins Tom20 and Tom22 in mice overexpressing GPx4. These data suggest that selenium supplementation and/or upregulation of GPx4 expression protect mitochondrial function and may be beneficial in PD patients.

Title: Alpha synuclein binds tom20 and impairs mitochondrial protein import in parkinson’s disease

Authors: *P. BARRETT[1], R. DIMAIO[1], E. HOFFMAN[1], C. BARRETT[1], A. ZHARIKOV[1], C. CHU[2], E. BURTON[1], T. HASTINGS[1], J. GREENAMYRE[1];

Abstract: α-synuclein and mitochondrial impairment have both been implicated in the pathogenesis of Parkinson's disease (PD). Mitochondrial dysfunction leads to accumulation, oligomerization and aggregation of synuclein. Conversely, overexpression of synuclein leads to mitochondrial impairment by unknown mechanisms. We report that certain modified forms of synuclein interact specifically with the TOM20 receptor for mitochondrial protein import. Using a proximity ligation assay, we show that this interaction is blocked competitively by expression of a mitochondrial targeting sequence (MTS) peptide, the normal ligand of TOM20. Using mitochondrial protein import assays, we demonstrate that this interaction is sufficient to block MTS-mediated protein import. To investigate the roles of post-translational modifications of synuclein in this effect, we added monomeric synuclein, oligomeric WT synuclein, dopamine (DA)-modified synuclein, nitrated synuclein and an S129 phosphomimetic synuclein mutant to cells. Monomeric and nitrated synuclein had little effect, while oligomeric, DA-modified and phosphomimetic synuclein potently inhibited import. Inhibition of mitochondrially targeted proteins resulted in a decrease in mitochondrial respiration and complex I activity and an increase in oxidative stress. Using fluorescence spectroscopy, we measured direct binding of synuclein to the cytoplasmic domain of TOM20 and found specific binding ($K_d < 5\mu M$) of oligomeric, DA-modified and phosphomimetic synuclein, but not monomeric or nitrated species. Blinded postmortem assessment of human substantia nigra specimens revealed a strong association between synuclein and TOM20 in PD cases compared to controls, with an associated loss of a mitochondrially imported complex I subunit. To determine the extent to which endogenous synuclein contributes to the toxicity of mitochondrial impairment *in vivo*, we used a viral vector to knock down synuclein in substantia nigra and exposed rats to rotenone. Synuclein knockdown prevented the synuclein-TOM20 interaction and preserved levels of mitochondrially imported protein. Lastly, we showed that overexpression of TOM20 preserves mitochondrial protein import in the presence of oligomeric, DA-modified, and phosphomimetic synuclein. We conclude that post-translationally modified alpha-synuclein specifically interacts with the TOM20 receptor to inhibit mitochondrial protein import, resulting in senescent mitochondria that produce less energy and more reactive oxygen species. Thus, we have uncovered a novel pathogenic mechanism in PD that may provide a new target for therapeutic intervention.

Abstract: Parkinson's disease (PD) is a common, progressive, neurodegenerative disorder that currently afflicts almost 2% of the population over 65 years of age. This number is expected to double by 2030. While motor dysfunction, resulting from the loss of dopaminergic (DAergic) neurons in the substantia nigra, is a cardinal feature of PD, the majority of individuals with PD experience non-motor symptoms with cognitive dysfunction being one of the most prominent and debilitating non-motor symptom. Such co-morbidities in PD are unrelated to the loss of DAergic neurons since they are not resolved by DAergic therapy. The current view is that α-synuclein (αS) pathology in the cortex and hippocampus may be responsible for the dementia in PD as well as in Dementia with Lewy Bodies (DLB), a disease highly related to PD. Together, PD and DLB comprise the second leading cause of dementia behind Alzheimer's disease. Thus, overcoming the limitations of current treatments and therapies to address this clinical burden relies on a better understanding of disease pathophysiology.
To elucidate the mechanisms underlying αS-mediated cognitive dysfunction in PD, we utilized transgenic (Tg) mice overexpressing wild-type (WT) human αS or αS harboring familial PD-linked mutations (A53T or A30P mutation). Cohorts of Tg mice and their non-Tg littermates were subjected to a variety of behavioral, electrophysiological and biochemical assays at defined ages up to one year old. We first demonstrate, using Barnes Maze and Fear Conditioning, that mice expressing the A53T mutant human αS (termed G2-3) display progressive memory impairment that precedes the onset of motor deficits. Consistent with the lack of overt pathology,

Tg mice expressing WT and A30P mutant human αS do not show memory impairment at 12 months of age. We explored whether the memory deficits could be linked to αS-induced synaptic deficits in hippocampal slices. Our analysis reveal that all three human αS Tg lines exhibit reduced number of spontaneous synaptic activity, consistent with αS being a general regulator of presynaptic function. Significantly, slices from A53T mutant αS Tg mice also showed reduced amplitude of spontaneous synaptic activity and reduced AMPA:NMDA ratio, suggesting a postsynaptic pathophysiology unique to this mutation. Taken together, our results provide a potential novel mechanism for αS-dependent regulation of synaptic activity where pathologic αS, such as the A53T mutant αS induces postsynaptic changes and cognitive impairment *in vivo*.

Abstract: Introduction: Parkinson’s disease (PD) is the second most common neurodegenerative disorder around the world. It is characterized by the loss of dopaminergic neurons of the *substantia nigra pars compacta* and striatal dopamine deficiency. Several reports in the literature indicate that neuronal death in PD occurs as a result of oxidative damage, due to an imbalance of free radicals to antioxidant mechanisms. Under these conditions of free radicals' overproduction, programmed cell death (apoptosis) can be started. The dynamics of that apoptotic cell death is unknown. Thus, the aim of this work was to determine the time-course of

the caspase 3 and caspase 9 activities, as markers of apoptosis in a model of PD induced by MPP+ in rats. **Experimental procedures:** Male Wistar rats (250-280 g of body weight) were used throughout the study. MPP+ iodide dissolved in sterile saline (10μg/8μL) was intrastriatally microinjected, using an stereotaxic frame. We used the following stereotaxic coordinates: 0.5 mm anterior to bregma, -3.0 mm lateral to bregma and -4.5mm ventral to the dura in the right striatum. The animals were killed by decapitation at 24, 48, 72, 120 and 168 hours after MPP+-injection to establish the time-course for maximal activity of caspases 3 and 9 in the striatum. **Results** showed an increased activity of both caspase 9 (28.3 ± 7.4) and caspase 3 (176.3 ± 26.6) at 120 hours after MPP+, as the highest value of caspase activation after injection. **Discussion;** The findings of this study allowed us to identify the time course of caspase activation after MPP* to further characterize the kinetics of apoptosis, that in turn may help us to develop neuroprotective strategies in the model of Parkinson´s disease. Title: Chronic psychological stress promotes PINK1/parkin-mediated mitophagy in mouse amygdala

Authors: ***K. DUAN**[1], X. LIU[2], Z. LI[1];
[1]Natl. Inst. of Mental Hlth., Bethesda, MD; [2]Key Lab. of Med. Neurobio. and Pharmacol. Res. Ctr., Fudan Univ., Shanghai, China

Abstract: Mitophagy is a specialized autophagy pathway that mediates the removal of damaged mitochondria by lysosomes for mitochondrial quality control. Since mitochondria are vulnerable to stress, mitophagy under stress conditions may play an important role in the stress-related psychopathology. Here we report that exposure of mice to chronic psychological stress correlates closely with the development of mitochondrial dysfunction in the amygdala, which in turn recruits PINK1/parkin-mediated mitophagy. Our results showed that mitochondria manifest abnormalities at the molecular, structural and functional levels particularly in amygdala after exposure to chronic social defeat stress (CSDS) 30 days. The mtDNA copy number in amygdala is significantly decreased (50.99%) at CSDS 30 days, but unchanged at CSDS 10 days. The stress enhances parkin or LC3 translocation to mitochondria and mt-KeimaRed translocation to

lysosomes in basolateral amygdala (BLA). Moreover, the PINK1 and parkin protein expressions are increased in homogenate of amygdala tissue after CSDS (154.77% and 136.33%). Thus the mitochondrial dysfunction and subsequent mitophagy in amygdala are potentially involved in the psychological stress-related psychopathology.

Title: Paraquat and stress interactions as pertains to Parkinson disease motor deficits and co-morbid behaviors

Authors: *K. FARMER, C. RUDYK, Z. DWYER, J. MCNEILL, F. WAHBEH, N. PROWSE, S. HAYLEY;
Neurosci., Carleton Univ., Ottawa, ON, Canada

Abstract: The impact of psychological stressors on the progression of motor and non-motor disturbances observed in Parkinson's disease (PD) has previously received little attention. Animal models have demonstrated that chronic unpredictable stress models recapitulate core symptoms of anxiety and depression in addition to altering central inflammatory and neurochemical processes. These alterations may increase vulnerability in PD-relevant brain regions, increasing susceptibility to further insults. Interestingly, chronic stress has been found to exacerbate the neurochemical and behavioral disturbances induced by 6-hydroxydopamine (6-OHDA), however, whether the impact of the PD relevant pesticide paraquat is enhanced in the context of chronic stressor exposure has yet to be examined. In the current study we examined the effects of chronic stress on behavioral disturbances induced by sub-chronic paraquat administration. We found that paraquat exposed animals with a backdrop of chronic stress did not significantly alter motor behaviors compared to animals receiving paraquat alone, however, these animals did display reductions in sucrose preference earlier than animals who received paraquat alone. In addition, the combined treatment also resulted in cognitive and anxiety disturbances greater than those produced by stress of paraquat alone. Furthermore, post-mortem

analysis revealed that paraquat affects stress-sensitive brain regions as alterations in glucorticoid receptor expression in the hippocampus and plasma corticosterone levels were seen, an effect that was exacerbated when in the presence of a chronic stressor. These results suggest that chronic stress may interact with paraquat exposure to produce behavioral disturbances.

Title: GBA1 deficiency plays a role in the formation of physiological α-synuclein tetramer

Authors: ***S. KIM**, S. YUN, S. LEE, H. KO;
Neurology/ICE, Johns Hopkins Univ., Baltimore, MD

Abstract: Accumulating evidence suggests that α-synuclein occurs physiologically as a helically folded tetramer that resists aggregation. However, the mechanisms underlying the regulation of formation of α-synuclein tetramer are still mostly unknown. Cellular membrane lipids are thought to play an important role in the regulation of α-synuclein tetramer formation. Since GBA1 deficiency contributes to the aggregation of α-synuclein and leads to changes in the neuronal glycolsphingolipids (GSLs) including gangliosides, we hypothesized that GBA1 deficiency may affect the process of the α-synuclein tetramer formation. Here, we show that accumulation of GSLs due to GBA1 deficiency decreases the α-synuclein tetramer and increases α-synuclein monomer in neurons carrying heterozygous L444P GBA1 mutation. Moreover, the α-synuclein tetramer is decreased in N370S GBA1-PD iPSC-derived human dopaminergic neurons, CRISPR-GBA1 knockout SH-SY5Y cells, and stable SH-SY5Y cell lines expressing L444P GBA1. Strikingly, treatment of miglustast to reduce GSLs accumulation and overexpression of GBA1 to augment GBA1 activity reverse the destabilization of α-synuclein tetramer formation and protects against α-synuclein preformed fibrils induced toxicity in those cells. Taken together these studies could provide new mechanistic insights into how GBA1 deficiency due to GBA1 mutations contributes Parkinson's disease (PD) and Dementia with Lewy Body (DLB) and lead to unique therapeutic opportunities for PD and DLB.

Title: Effect of trans fatty acid on alpha synuclein channels and implications in Parkinson's Disease

Authors: ***S. SRIDHAR**, A. K. BERA;
Dept. of Biotech., Indian Inst. of Technol. Madras, Chennai, India

Abstract: Dietary *trans* fatty acids (TFAs) are known to increase the risk of heart attack. However, their role in neurodegenerative diseases is not clear. We studied the effect of elaidic acid, the most abundant TFA found in food, on channel forming properties of alpha synuclein (ASN). ASN has been implicated in Parkinson's disease. The oligomeric species of ASN has been shown to be the toxic species which spreads the neuronal damage. Human ASN oligomers readily formed channels in planar lipid bilayer (PLB), composed of diphytanoyl phosphatidyl choline (DPhPC) and oleic (*cis*) or elaidic (*trans*) acid. When elaidic acid was incorporated in PLB, ASN channels exhibited different properties. The channels showed frequent but brief closures and longer open times in membranes with TFA as compared to *cis* lipid containing membranes. Also, the single channel conductance was greater in channels in TFA containing membranes with respect to those in *cis* lipid membranes. We are currently investigating the ASN toxicity in cultured neuron, pretreated with TFA. In conclusion, having TFAs in neuronal membranes could potentially exacerbate the neurodegeneration that occurs in Parkinson's disease.

Title: Self-defense responses against 6-hydroxydopamine-induced nitrosative cell death in C6 glioma cells

Authors: H. MOON[1], C. LEE[2], G. PARK[1], *J.-H. JANG[2];
[1]Col. of Pharm., Kyungpook Natl. Univ., Daegu, Korea, Republic of; [2]Dept. of Pharmacol., Keimyung University, Sch. of Med., Daegu, Korea, Republic of

Abstract: Parkinson's disease (PD) is a neurodegenerative disease, which is caused by degeneration of dopaminergic neurons in the substantia nigra. As an experimental cellular model of PD, 6-hydroxydopamine (6-OHDA), a representative dopaminergic neurotoxin is widely used to cause an oxidative cell death in neuronal cells. In the present study, we have investigated 6-OHDA-induced neuronal cell death focusing on the nitrosative stress and accompanying adaptive survival responses in C6 glioma cells. Treatment of C6 cells with 6-OHDA increased expression of inducible nitric oxide synthase and subsequent production of nitric oxide. Furthermore 6-OHDA treatment led to formation of peroxynitrite and nitrotyrosine. 6-OHDA-induced nitrosative stress ultimately caused apoptotic cell death as determined by decreased Bcl-2/Bax ratio, activation of c-Jun N-terminal kinase, and cleavage of caspase-3 and poly(ADP-ribose)polymerase, which were attenuated by peroxynitrite decomposition catalyst, 5,10,15,20-tetrakis(4-sulfonatophenyl)porphyrinato iron(III). In addition, exposure of C6 cells to 6-OHDA resulted in an increased expression of heme oxygenase-1 (HO-1) and 6-OHDA-induced cytotoxicity was effectively suppressed by carbon monoxide which is known to be produced by HO-1, supporting the cytoprotective role of HO-1. To elucidate the molecular mechanism underlying 6-OHDA-mediated HO-1 induction, we have examined the possible involvement of NF-E2-related factor 2 (Nrf2), which plays an important role in the transcriptional regulation of phase II detoxifying and antioxidant enzymes. 6-OHDA treatment increased nuclear translocation and transcriptional activity of Nrf2, which seemed to be partly mediated by activation of upstream kinases such as Akt/protein kinase B (PKB). Taken together these findings suggest that HO-1 up-regulation via Nrf2 activation may mediate the cellular adaptive survival response to 6-OHDA-induced nitrosative cell death in C6 glioma cells.

Abstract: Parkinson's disease (PD) is a progressive neurodegenerative disease and is due to the degeneration of dopaminergic neurons in the brain. Neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) metabolite 1-methyl-4-phenylpyridinium (MPP^+) activate glial cells and release several inflammatory mediators in PD. We have previously shown that brain protein glia maturation factor (GMF) and mast cells are implicated in neuroinflammation and neurodegeneration. Matrix metalloproteinases (MMPs) including MMP-3 is involved in neurodegeneration and mast cells are known to secrete MMP-3. Moreover, mast cell mediator mouse mast cell protease-6 (MMCP-6) and MMCP-7 could activate glial cells and neuronal cells in neurodegenerative diseases. However, how mast cells, glial cells and neurons interact with each other during neuroinflammatory response such as in PD is not yet clearly understood. In this study, we analyzed the effect of MPP^+, GMF or mouse mast cell proteases on mouse bone marrow-derived cultured mast cells (BMMCs) and mouse fetal brain-derived cultured brain cells on the release of inflammatory mediators MMP-3 and chemokine (C-C motif) ligand 2 (CCL2), and the expression of co-stimulatory molecules CD40 and CD40L (CD154) in glial cells and mast cells co-culture system. Inflammatory mediators were quantitated in the cell culture supernatant media by ELISA and the expression of co-stimulatory molecules were analyzed on the cultured cells by flow cytometry. MPP^+ and GMF induced the release of MMP-3 from BMMCs. MMCPs induced the release of MMP-3 as well as CCL2 from mouse astrocytes. Flow cytometry results showed increased CD40L expression by MPP^+ in BMMCs, in a co-culture system that consisted of both BMMCs and mouse glial cells. Similarly, GMF increased the expression of CD40 in astrocytes, in an astrocyte plus BMMCs co-culture system. In conclusion, our results indicate potential new therapeutic target for neurodegenerative diseases including PD.

Title: Selective Toll-like receptor inhibition occludes alpha-synuclein-induced pro-inflammatory signaling & cytokine release

Authors: ***A. M. HABAS**[1], S. NATALA[2], J. WONG[2], W. WRASIDLO[2], M. GILL[3], D. BONHAUS[3];
[1]In Vitro Pharmacol., Neuropore Therapies, Inc., San Diego, CA; [2]Neuropore Therapies Inc., San Diego, CA; [3]Neuropore Therpaies Inc., San Diego, CA

Abstract: Synucleinopathies are a family of central nervous system (CNS) degenerative disorders characterized by deposition of insoluble alpha-synuclein-containing protein aggregates, neuronal and/or glial cell death and inflammation. Toll-like receptors (TLRs) play a critical role in innate immune system response to damage-associated molecular patterns (DAMPs) and pathogen-associated molecular patterns (PAMPs). DAMP/PAMP-mediated activation of TLR1/TLR2 or TLR2/TLR6 heterodimers triggers NFκB signaling resulting in pro-inflammatory cytokine release. Recently, secreted, high molecular weight (HMW) alpha-synuclein aggregates derived from over-expressing rodent neuroblastoma cells have been shown to stimulate pro-inflammatory signaling in CNS-derived microglia. Genetic- or antibody-mediated TLR2 inhibition occluded this signaling cascade, suggesting TLR2 inhibition may be a viable strategy to disrupting alpha-synuclein-mediated inflammation. Here using stable TLR2-expressing HEK and naïve monocyte/macrophage-derived heterologous cell lines, we confirm that HMW alpha-synuclein activates pro-inflammatory signaling. In addition, we show, using blocking antibodies, that specific inhibition of TLR1/TLR2 but not TLR2/TLR6 occludes alpha-synuclein-mediated pro-inflammatory signaling. Lastly, we show that TLR2-selective small molecules inhibit alpha-synuclein-mediated pro-inflammatory signaling, supporting TLR2-selective small molecule inhibition as a feasible therapeutic modality towards blocking alpha-synuclein-mediated CNS inflammation.

Title: Glia maturation factor dependent activation of nod like receptor family pyrin domain containing 3 (NLRP3) inflammasome

Authors: H. JAVED[1], M. M. KHAN[1], R. THANGAVEL[2], K. DURAISAMY[2], S. ZAHEER[2], S. IYER[2], *A. ZAHEER[2];
[1]Neurol., Univ. of Iowa, Iowa City, IA; [2]Neurol., Univ. of Missouri & Truman VA, Columbia, MO

Abstract: Neuroinflammation is a major contributor to the pathogenesis of various neurodegenerative diseases including Parkinson's disease (PD). Mice treated with 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) exhibits microglial activation-induced inflammation, and nigrostriatal dopaminergic (DA) neuronal damage, and thus serve as an experimental model of PD. Nod-like receptor family pyrin domain containing 3 (NLRP3) is a key component of the macromolecular signaling complex called NLRP inflammasome that promotes caspase-1 dependent maturation of pro-IL-1β followed by cell death. Glia maturation factor (GMF) a proinflammatory protein that is up-regulated in the central nervous system in neurodegenerative conditions. In the present study, we have investigated the expression of NLRP3 and caspase-1 in the substantia nigra (SN) of human PD and non-PD brain by immunohistochemistry. NLRP3 and caspase-1 positive cells were found significantly increased in PD when compared to non-PD control brains. We further detected the expression of NLRP3 inflammasome in the glial cells following MPTP treatment in mice. GMF deficient mice ($GMF^{-/-}$) showed reduced expression of NLRP3 inflammsome in the glial cells of SN as compared to WT. Subsequently, we found IL-1β level was significantly increased in the mid brain of WT as compared to $GMF^{-/-}$ mice. We demonstrated the possibility that GMF-dependent activation of the NLRP3 inflammasome is involved in the maturation of IL-1β in MPTP-treated mice. Our overall data indicate that GMF deficiency is crucial for the survival of DA neurons, by modulating the NLRP3 inflammsome activation, in animal model of PD.

Title: Effect of chronic systemic inflammation in the cytokines profile in central nervous system and its implication in suceptibility to damage by neurotoxin MPTP in mice

Authors: *P. UGALDE MUÑIZ[1], A. CHAVARRÍA KRAUSER[2];
[2]Neuroinmunología, [1]Hosp. Gen. De México, Ciudad De México, Mexico

Abstract: Inflammatory processes and activation of microglia are both important factors in the pathogenesis of Parkinson's disease (PD). Recent studies demonstrated that systemic inflammation and neuroinflammation are both present in the progression of the disease. Evidence suggests that the activation of the peripheral immune system exacerbates the brain inflammatory response, which may initiate or enhance neurodegenerative processes. Recent data suggest that activation of the innate immune system, such as evoked by a peripheral pathogen, stimulates the pathogenesis of PD by generating a transient pro-inflammatory environment that is likely to accelerate neurodegeneration. The purpose of this work is to determinate if chronic systemic inflammation increases the inflammatory response in central nervous system in mice, and if this chronic inflammatory state turns animals more susceptible to damage by the neurotoxin MPTP. CD1 mice were used testing two strategies with LPS: 5 mg/kg i.p. (single dose) or 100 μg/kg i.p. (chronic dose) twice a week for three months. Both single and chronic doses were followed by MPTP intoxication (5 mg/kg i.p. for five days). To discern between the mechanisms of inflammation transfer from the periphery to the brain and the neurodegenerative consequences, levels of TNFα, IL-6, IL-10, and TGF-β were evaluated by ELISA in plasma and brain. As well as mitochondrial viability in the brain was evaluated by the assay of MTT reduction. Our results showed that chronic administration of LPS (100 μg/kg) decreased mitochondrial viability in the brain and increased levels of IL-6, TNFα, and TGF-β in both plasma and brain. The single dose of LPS (5 mg/kg) decreased mitochondrial viability in the brain as well; however, no changes were observed in the cytokine profile in the brain or plasma. On the other hand, the chronic dose of LPS together with MPTP increased IL-6 and TNFα, but not IL-10 and TGF-β in both plasma

and brain when compared with the group administered only with MPTP. In contrast, the single dose of LPS with MPTP evoked a raise in TNFα levels only in the brain. Our data suggest that a chronic inflammatory environment may associate with the progression of PD. We proved that the administration of systemic LPS could evoke an increase in the pro-inflammatory citokine profile, but not of anti-inflammatory cytokines. We believe that this previous chronic pro-inflammatory state may cause a susceptibility to a second inflammatory stimulus, exacerbating the pro-inflammatory cytokine production and reducing the anti-inflammatory mechanisms, all of this together could result in the death of dopaminergic neurons.

Title: Differential gene expression profile between early and late stage disease model of Parkinson's disease

Authors: *A. VERMA, V. RAVINDRANATH;
Ctr. for Neurosci., Indian Inst. of Sci., Bangalore, India

Abstract: The characteristic death of dopaminergic neurons in substantia nigra pars compacta(SNpc) leads to Parkinson’s disease(PD), a debilitating movement disorder. Although several putative mechanisms have been implicated in neuronal degeneration in SNpc, the factors that trigger selective cell death of dopaminergic neurons remain elusive. We therefore aimed to investigate the changes in gene expression from the early to late stage of disease pathogenesis using 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine(MPTP) administered to mice sub-cutaneously at 30mg/kg body weight as a model of PD. Gene expression profiles were examined using RNA seq from SNpc at the early stage, 24 hrs post single exposure to MPTP and late stage, that is post 14 days of daily MPTP treatment where SNpc has undergone substantial cell death. The raw reads were taken through quality check using FastQC and were trimmed and filtered using Trimmomatic. They were aligned to mouse reference genome using TopHat2 and counts were assigned to the genetic loci using HTSeq. The data was further analysed for differential

expression of genes and miRNAs using DESeq2 and for differential exon usage and expression using DEXSeq. In addition, gene set enrichment analysis was performed on the data from both stages of disease pathogenesis using GAGE. Interestingly, it was observed that the expression of Nurr1, an important regulator of dopaminergic phenotype is down-regulated in the early stage of PD-disease pathogenesis and the down-regulation persists in late stage of disease. Dopaminergic neuronal markers such as tyrosine hydroxylase(TH), dopamine transporter(DAT), vesicular monoamine transporter(VMAT) and dopamine receptor D2 showed decreased gene expression only in the late stage implying cell death at this stage. Our results indicate that several pathways ranging from those involved in protein translation, splicing, oxidative phosphorylation, tumor necrosis factor α(TNFα) signalling etc. are perturbed early in the disease process and may play a role in initiating neurodegeneration in SNpc. RNA seq provides a reliable high throughput method for discovering perturbation in global gene expression networks thus providing insights into pathogenic processes.

Title: Diamide induces selective and progressive dopaminergic neurodegeneration, α-synuclein pathology and Parkinsonism in mice: A model of Parkinson’s disease

Authors: *A. RAY, A. VERMA, S. KUMAR, V. RAVINDRANATH;
Ctr. for Neurosci., Indian Inst. of Sci., Bangalore, India

Abstract: Oxidative stress has been demonstrated to play a critical role in pathogenesis of Parkinson’s disease (PD). We have shown that oxidative modifications of thiols, resulting in disruption of thiol homeostasis can trigger degeneration of dopaminergic neurons in substantia nigra *pars compacta* (SNpc). To test for specificity of degeneration, we stereotaxically administered a single, unilateral dose of the thiol oxidant, diamide, into either mouse SN or motor cortex. While SN injected mice demonstrated locomotor deficits and neurodegeneration in SNpc, similar defects were not observed upon diamide administration into motor cortex

indicating that SNpc neurons are highly vulnerable to thiol oxidation mediated by diamide. Mice injected with single dose of diamide into SN showed hemiparkinsonian motor impairment, which was accompanied by significant time-dependent progressive loss of dopaminergic neurons in ipsilateral SNpc and their striatal fibers. Frank neurodegeneration was confirmed by increased Fluoro-Jade C staining and loss of NeuN positive neurons. Importantly, diamide injection led to α-synuclein aggregation in ipsilateral SNpc, a hallmark of PD pathology not often seen in animal models of PD. Increased punctate phospho-α-synuclein and ubiquitin staining in SNpc cells further supported pathological α-synuclein aggregation. We observed loss of glutathione, essential for maintaining thiol homeostasis, coupled with increased lipid peroxidation, suggestive of ongoing oxidative stress. Concomitantly, the ASK1-p38 MAPK death signaling pathway was activated in ipsilateral but not contralateral ventral midbrain through oxidation of Trx1 and dissociation of ASK1-Trx1 complex. Since diamide selectively disrupts thiol homeostasis, dopaminergic neurons appear to be vulnerable to such perturbations, such that even a single exposure to thiol oxidant results in long-lasting progressive degeneration. Understanding the impact of thiol perturbation in neurodegeneration, especially in early PD, will not only reveal novel regulatory mechanisms of cellular signaling, but may aid in developing disease-modifying strategies for PD as well.

Title: Dopaminergic degeneration following viral mediated dysregulation of dopamine: Implications for Parkinson’s disease

Authors: ***M. BUCHER**, C. W. BARRETT, T. G. HASTINGS;
Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Dopaminergic neuronal health is dependent upon the proper handling of dopamine (DA). Following synthesis in the cytosol, DA is quickly packaged into acidic vesicles via the

vesicular monoamine transporter 2 (VMAT2). Disruptions in the packaging of DA can lead to increased cytosolic DA oxidation, forming ROS and highly reactive DA quinone, which can attack and covalently modify protein cysteinyl residues leading to detrimental downstream consequences. Cytosolic DA oxidation has been proposed to contribute to the neurodegenerative process in Parkinson's disease (PD). Previously, it was shown that mice expressing only 5% of normal VMAT2 levels showed an age dependent loss of substantia nigra (SN) DA neurons, and increased DA oxidation (Caudle et al.,2007). More recently, Pifl et al.(2014) showed impaired VMAT2 function within the remaining dopaminergic terminals in PD patients, suggesting that a dysregulation of DA storage can contribute to the pathogenesis of the disease. To investigate the effects of reduced VMAT2 expression in an adult animal, an adeno-associated virus containing a plasmid coding for small-hairpin ribonucleic acid against VMAT2 was generated (AAV2-sh[VMAT2]). Rats were stereotactically injected unilaterally into the right SN with AAV2-sh[VMAT2]. Six weeks following the viral injection, SN coronal sections were immunostained for VMAT2, tyrosine hydroxylase (TH), MAP2 and DAPI. Stereological counting of TH-and MAP2-positive neurons showed a significant loss of SN DA neurons on the AAV2-sh[VMAT2] injected side (-38.74%) compared to the contralateral non-injected SN ($N=5$; $p<0.05$). Likewise, decreased density of striatal TH-immunoreactive terminals and the presence of dystrophic axons on the viral injected side also suggested neurodegeneration. In the remaining transduced TH-positive SN neurons, VMAT2 protein levels were significantly decreased, and there was an increase in insoluble α-synuclein. Consistent with the loss of DA neurons, rats injected unilaterally into SN with AAV2-sh[VMAT2] showed significant asymmetric motor deficits as determined by the postural instability test and the cylinder test. These results show that a substantial reduction in the expression of VMAT2 within dopaminergic neurons is sufficient to cause neurotoxicity, implicating proper VMAT2 functioning and DA sequestration in the maintenance of dopaminergic neuronal health.

Title: Impaired autophagy in Huntington´s disease impacts on global microRNA-levels through Argonaute-2 accumulation

Authors: *K. PIRCS[1], R. PETRI[1], S. MADSEN[1], P. L. BRATTÅS[1], M. MATUSIAK-BRÜCKNER[1], R. VUONO[2], N. DÉGLON[3], R. A. BARKER[2], J. JAKOBSSON[1];

Abstract: Many neurodegenerative disorders, such as Huntington's disease, are characterised by the formation of protein aggregates in the brain. However, despite intense research it remains still unclear if and how protein aggregation is implicated in the neuronal cell death. In this project we investigate a potential link from protein aggregation to cell death via autophagy and microRNAs in models of Huntington's disease.
To confirm that aggregation of mHTT protein results in impaired autophagy in the brain, we generated AAV vectors expressing mHTT with 66 CAG repeats and performed injections in the striatum of adult mice. We found that expression of mHTT resulted in time-dependent aggregation of mHTT that was associated with reduced levels of DARPP32 a marker of medium spiny neurons decreased in HD brains. Animals injected with mHTT displayed an induced autophagy 10 days after injection that were reversed at 3 and 8 weeks when autophagy was impaired. We found significantly more p62 by time coupled with elevated LC3-II levels suggesting a later autophagic block with autophagic flux impairment. In line with this, we found that mRNA-levels of transcription factors that activate autophagy were up regulated in mice 10 days after injection but at 3 weeks we saw the opposite, all the enhancers were down regulated. We also found an interesting trend for genes involved in lysosomal biogenesis, autophagosome maturation, cargo recruitment and vesicle trafficking: the fold changes of the mHTT/wtHTT mRNA levels were reversed. In almost all cases mRNA levels that were up regulated by 10 days after autophagy activation were decreased after 3 weeks due to autophagy impairment and vice versa.
Furthermore, we investigated a potential link between impaired autophagy and miRNA biogenesis in the mHTT mice and found an increased AGO2 protein level. AGO2 plays a central role in RNA silencing processes and it has been previously shown that selective autophagy degrades AGO2 and regulates miRNA activity. Furthermore, we found that mHTT expression and high AGO2 levels in mouse striatal neurons alters global levels of neuronal miRNAs. Additionally, we also observed that overexpression of BECN1 reverses mHTT-associated phenotypes by partially preventing aggregation of mHTT, decreasing the number of p62 aggregates and also reducing AGO2 aggregate size and number.
Overall, our data shows that mHTT aggregates impair autophagy on a protein and on a transcriptional level. Furthermore, we have shown that mHTT impairs clearance of protein aggregates and also alters the function of cellular cascades such as miRNA biogenesis.

Title: Respiration and Ca^{2+} handling by striatal mitochondria purified from brains of YAC128 mice, a model of Huntington's disease.

Authors: ***J. HAMILTON**[1], T. BRUSTOVETSKY[1], N. BRUSTOVETSKY[1,2];

Abstract: Huntington's disease (HD) is a hereditary neurodegenerative disorder characterized by motor and cognitive abnormalities and extensive striatal degeneration. HD pathogenesis is linked to a mutation in the protein huntingtin (Htt), which is normally involved in developmental processes and trafficking. The mechanistic link between mutant huntingtin (mHtt), selective striatal vulnerability, and HD pathogenesis is unknown. Previously, it was proposed that mitochondrial dysfunction could contribute to HD pathogenesis. In our previous studies with mitochondria isolated from YAC128 mice that express full-length human mHtt and R6/2 mice that express the exon 1-encoded fragment of human mHtt, we found no evidence for functional deficits in mitochondria from HD mice compared with mitochondria from WT mice. However, in these studies we evaluated functions of mitochondria isolated from the whole brain. In the present study, we investigated the effect of mHtt on respiration and Ca^{2+} uptake capacity of mitochondria isolated from striata of YAC128 mice. We genotyped every mouse to confirm the presence of the transgene and analyzed isolated mitochondria by western blotting for the presence of mHtt. We evaluated respiratory activity in Percoll gradient-purified nonsynaptic and synaptic striatal mitochondria from 2 month old, early symptomatic YAC128 mice and age-matched WT mice. We used western blotting to evaluate the expression of nuclear-encoded mitochondrial proteins in striatal mitochondria: 39 kDa subunit of Complex I, 30 kDa subunit of Complex II, 70 kDa subunit of Complex II, Aconitase 2, manganese-dependent superoxide dismutase, alpha subunit of ATP synthase, Cyclophilin D, and subunit IV of cytochrome *c* oxidase. We also assessed the effect of mHtt on Ca^{2+} uptake capacity in nonsynaptic and

synaptic striatal mitochondria isolated from YAC128 mice. In our experiments, we found no difference in respiratory activity and Ca^{2+} uptake capacity between striatal mitochondria from YAC128 mice and WT animals. The lack of mitochondrial dysfunction was supported by comparable expression of nuclear-encoded mitochondrial proteins in striatal mitochondria from YAC128 and WT mice. Overall, our data do not support mHtt-mediated impairment of mitochondrial respiratory activity and Ca^{2+} handling in striatal mitochondria from YAC128 mice.

Abstract: Huntington disease (HD) is a neurodegenerative disorder strongly affecting the striatum and the cerebral cortex. HD is caused by a CAG expansion in the *HTT* gene encoding for mutant huntingtin (mHTT), which affects mitochondrial function and redox regulation, leading to oxidative stress. In this study we assessed mitochondrial deregulation and modified redox changes in HD through *in vivo* PET brain studies for detection of oxidative stress using

radiolabeled Cu(II)-ATSM and *ex vivo* mitochondrial function and bioenergetic analysis of brain mitochondria isolated from pre-symptomatic (3 month-old, mo) and symptomatic stages (6-12mo) YAC128 transgenic mice *versus* age-matched wild-type mice. YAC128 mice at initial symptomatic stages exhibited an increase in Cu(II)-ATSM uptake in striatum and, at a lower extent, in hippocampus, but not in pre-frontal cortex. Because Cu(II)-ATSM uptake has been attributed to mitochondrial-associated oxidative stress, we analyzed the production of hydrogen peroxide (H_2O_2) in striatal and cortical mitochondria of YAC128 mice. Interestingly, 3mo YAC128 mice striatal mitochondria exhibited higher H_2O_2 production rate. In cortex, H_2O_2 production was significantly increased in YAC128 mitochondria at 12mo, along with decreased catalase protein levels. Moreover, pre-symptomatic YAC128 striatal mitochondria exhibited an increase in both O_2 consumption rate and respiratory chain complexes I-IV activities, whereas a significant decrease in these parameters was observed in cortical YAC128 mitochondria. Mitochondrial Ca^{2+} handling also increased in YAC128 striatal mitochondria, but was reduced in the cortex of 3mo YAC128. In striatum of 9mo YAC128 mice an increase in mitochondrial coupling was observed, without changes in complexes I-IV activities. At old symptomatic stage (12mo) no major differences in mitochondrial function were observed either in cortex or striatal mitochondria. In sum, we found evidence for bioenergetics defects occurring in pre-symptomatic YAC128 mice, namely decreased mitochondrial function in the cortex and enhanced organelle activity in striatum, which is accompanied by *in vivo* decreased redox status.

Title: Mutant huntingtin disrupts the nuclear pore complex

Authors: *J. C. GLATZER[1], J. C. GRIMA[2], K. ZHANG[2], J. DAIGLE[2], Q. PENG[2], C. GEATER[3], I. AHMED[2], C. ROSS[2], W. DUAN[2], L. THOMPSON[3], S. H. SNYDER[2], J. D. ROTHSTEIN[2];
[1]Neurosci., Univ. of Rochester, Staten Island, NY; [2]Johns Hopkins Neurosci., Baltimore, MD; [3]Univ. of California, Irvine, Irvine, CA

Abstract: Huntington's disease (HD) is caused by an expanded CAG repeat in the first exon of the huntingtin (htt) gene, resulting in progressive degeneration of striatal medium spiny neurons. Disease onset and severity are dependent on CAG repeat length with a longer expansion resulting in earlier onset and greater severity. The underlying mechanisms by which mutant htt causes the disease have not been fully elucidated. Recent studies suggest that nucleocytoplasmic transport dysfunction could be a pathogenic contributor.
The trafficking of RNA and proteins between the cytoplasm and the nucleus is a critical aspect of signal transduction and is especially arduous for neurons due to their highly polarized structure. This process is tightly regulated by Nuclear Pore Complexes (NPCs), which serve as the main gateway between the nucleus and cytoplasm. The NPC is one of the largest protein complexes in eukaryotic cells and consists of multiple copies of approximately 30 different protein subunits called Nucleoporins (NUPs). NUPs are organized into regions e.g. cytoplasmic ring/filaments, central channel, transmembrane, scaffold, nuclear ring/basket and each play roles in overall NPC transport function, such as mRNA export and protein import/export. Interestingly, it was recently discovered that some of the longest-lived proteins in the mammalian brain are NUPs located in the scaffold of the NPC and may represent the "weakest link" in the aging proteome.
Recent live-cell imaging studies show that mutant htt demonstrates reduced dynamics and rates of nucleocytoplasmic transport. Cell culture and transgenic animal models display distortions in nuclear envelope and increases in the clustering of NPCs. Studies have demonstrated that mutant htt can preferentially bind certain components of the NPC and that cytoplasmic protein aggregates can interfere with nucleocytoplasmic transport of protein and RNA. And finally, recent studies show that RAN translation products, which have been shown to disrupt nucleocytoplasmic transport in C9orf72 ALS-FTD, are also produced in HD. We hypothesize that products of the mutant htt repeat expansion are likely to disrupt nucleocytoplasmic transport at the NPC. To this end, we assessed NPC integrity in various transgenic HD mouse tissues, HD iPS neurons and postmortem human HD brain regions. Our data indicate that select NUPs involved in nucleocytoplasmic trafficking are affected as evidenced by nuclear aggregation that co-localizes with mutant htt. Functional studie sin iPS cell are ongoing. This study suggests that the NPC is disrupted in HD and potentially other repeat-expansion diseases.

Title: Integrated mitochondrial function in human muscle biopsies of Huntington's Disease patients and in different tissues of the HdhQ111 mouse model

Authors: *K. S. LINDENBERG[1], E. BARTH[1], T. MERZ[1], A. GUMPP[1], A. WITTING[1], P. WEYDT[1], M. ZUEGEL[2], J. STEINACKER[2], G. LANDWEHRMEYER[1], E. CALZIA[3]; [2]Div. of Sports and Rehabil. Med., [3]Inst. of Anesthesiological Pathophysiology and Process Develop., [1]Ulm Univ., Ulm, Germany

Abstract: The neurodegenerative genetic disorder of Huntington's disease (HD) is characterized by mitochondrial impairments of the respiratory chain. The ubiquitous expression of the disease causing mutant huntingtin gene raises the question to which extent changes in mitochondrial respiration are evident in the human skeletal muscle. In addition characterization of mitochondrial respiration in the muscle might allow conclusions about respiratory status in the brain.

The integrated respiratory chain function of the human quadriceps vastus lateralis was measured by high-resolution respirometry in fine needle biopsies of four pre-symptomatic HD mutation carriers and seven controls. The respiratory parameters indicated a trend towards a reduction in the respiratory control ratio (RCR) of the HD carriers. In parallel, murine cortex, liver, soleus muscle and heart of male HD knock-in mice (Hdh^{Q111}), which show a very mild phenotype, were examined by the same method. Significant changes of the respiration were restricted to the liver and the cortex. In addition mitochondrial DNA copy number and citrate synthase activity were determined to quantify the mitochondrial mass, showing no differences. From the murine tissues mRNA levels of key enzymes characterized the mitochondrial metabolic pathways. We demonstrated the feasibility to perform high-resolution respirometry measurements from fine needle human HD muscle biopsies. Furthermore, we conclude that differences in respiratory parameters of pre-symptomatic human muscle biopsies are rather limited, which is confirmed by the analysis of murine skeletal muscle tissue. The murine cortex and liver turned out to show respiratory changes in the Hdh^{Q111} mouse model, which indicates that respiratory capacities are different between tissues.

Title: Cortical mitochondria from R6/2 Huntington's disease mice have elevated iron and altered proteomic and functional markers.

Authors: ***S. AGRAWAL**, J. H. FOX;
Vet. Sci., Univ. of Wyoming, Laramie, WY

Abstract: Huntington's disease (HD) is a progressive autosomal dominant disorder caused by an expanded CAG repeat in exon 1 of the huntingtin gene. Dysregulation of iron homeostasis and energetic dysfunction are consistent features in HD mouse models. However, it is unclear if there is a connection between iron accumulation and energetic dysfunction in HD. The present study aimed to assess the relationship between mitochondria and iron dysregulation in R6/2 HD mice. Studies were completed in 12-week-old HD mice that had advanced HD and wild-type (WT) litter-mates. Inductively-coupled-plasma mass spectrometry (ICP-MS) analysis of iron levels in purified mitochondria revealed a 51.6% increase in HD mice ($p=0.0020$) compared to controls. We used a number of outcomes to characterize mitochondrial state. Mitochondrial membrane potential and ATP level were decreased by HD ($p=0.0086$ and 0.0120, respectively). Two-dimensional electrophoresis with matrix-assisted-laser-desorption-ionization (MALDI)-time-of-flight (TOF)/TOF was used to identify differentially expressed mitochondrial proteins. Preliminary analysis has identified seventeen proteins including peroxiredoxin 3, DJ-1, ATP synthase sub-unit β and isocitrate dehydrogenase 3 alpha. These proteins have functions linked with energy metabolism, carbohydrate metabolism, redox cycling, protein folding, the ubiquitin proteasome system and apoptosis. We conclude that elevations of iron in HD brain mitochondria are consistent with preferential accumulation in this organelle. Findings demonstrate co-localization of iron dysregulation and measures of mitochondrial dysfunction in R6/2 HD brain.

Sch., Berlin, Germany; [2]Dept. of Biol., [3]Dept. of Biol. Engin., MIT, Cambridge, MA; [4]Unité Neurosciences, Paris Seine INSERM, Paris, France

Abstract: Transcriptional dysregulation is an early and pivotal feature of Huntington's disease that is strongly reflected in mouse models of this disorder. We have previously demonstrated in *in vitro* and mouse models genome-wide changes in DNA methylation and histone H3K4 trimethylation patterns that may underlie transcriptional dysregulation in HD (Vashishtha et al., 2013; Ng et al., 2013). In the study reported here, centering on the prodromal disease stage, we discovered that the pathogenic transcriptional and epigenetic alterations in the brain in mouse models in fact precede the overt onset of disease symptoms. Genome-wide analysis of transcription by RNA sequencing (RNA-Seq) revealed many key neuronal genes such as Drd1a and Drd2, Penk and Adora2a whose disruption are significant in HD pathogenesis to be down-regulated in the R6/1 mouse striatum as early as 8 weeks of age. RNA-Seq in a second mouse model that is the full length *Huntingtin* model of CHL2 [Hdh(CAG)150] heterozygous knock-in mice validated the ongoing transcriptional dysfunction in the striatum during prodromal HD and confirmed a highly significant overlap of differentially-expressed genes between the R6/1 and CHL2 models even at this early disease stage (142 overlapping genes, $p < 3e\text{-}128$). Comparison with a human HD study (Kuhn et al., 2007) showed that gene expression changes in our mouse models were consistent in the caudate nucleus of postmortem brains from HD patients (162 genes in R6/1 ($p < 3e\text{-}54$) and 51 genes in CHL2 ($p < 1.3e\text{-}10$)). This provides strong evidence that these mice models faithfully recapitulate the transcriptional dysfunction in human HD and that a significant portion of the early transcriptional changes persist throughout the later disease stages. Extension of our studies to genome-wide analysis of histone H3K27 acetylation, an active transcription and enhancer mark, by chromatin immunoprecipitation followed by sequencing (ChIP-Seq) revealed highly coordinated ($p< 1.7e\text{-}10$) histone acetylation changes along with the

detected transcriptional changes in the striatum of R6/1 mice at 8 weeks of age. By studying the DNA sequences that lie within the altered H3K27 acetylation regions, we identified specific transcriptional regulators whose activity may be most proximally-altered by mutant *Huntingtin* consequently leading to the earliest transcriptional changes that we detected by RNA-Seq. The potential therapeutic value of targeting these predicted transcriptional regulators is currently ongoing in mouse models of HD.

Title: Aberrant CELF1 expression in Huntington's disease brain contributes to alternative splicing and changes in RNA stability.

Authors: *S. RAMACHANDRAN[1], S. COFFIN[2], B. L. DAVIDSON[2];
[1]Pathology, Children's Hosp. of Philadelphia, Philadelphia, PA; [2]The Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: CELF1 (CUGBP, Elav-Like Family Member 1) binds to highly conserved GU-rich elements (GREs) on target mRNAs and regulates gene expression by altering alternative splicing (AS) and RNA stability. CELF1's targets include RNA-binding proteins, transcription factors, and genes involved in neuronal differentiation, apoptosis, metabolism, and signal transduction. Evidence from invertebrate and vertebrate species implicate CELF1 in neurodegeneration, but it's role in normal or disease brain is not clear. Deep RNA-seq analysis of human Huntington's disease (HD) and control brains revealed significant up-regulation of CELF1 expression in HD samples. Further investigation showed that CELF1 protein is hyper-phosphorylated with increased stability and levels compared to controls in (i) the BA4 motor cortex from 20 HD patients, (ii) mature human neurons differentiated from iPSCs derived from 5 HD patients, (iii) striatum and cortex of the N171-82Q mouse model of HD (n=6), and (iv) cultured striatal neurons (STHdh-111Q). Furthermore, we found that CELF1 directly targets MBNL1 (Muscleblind-Like Splicing Regulator 1) mRNA for degradation, resulting in significantly reduced MBNL1 splicing activity in HD samples. We hypothesize that increased CELF1 activity

contributes to HD pathogenesis by altering expression of its splicing and RNA-stability targets. To address this we focused on the regulatory functions of CELF1 in the cortex of human HD brains and in the brains of HD mice models. Motif enrichment analysis of our RNA-seq data and candidate validation by high-throughput qPCR in CELF1 and MBNL1 knockout neuronal lines allowed prioritization of 120 direct targets of CELF1-mediated RNA stability or CELF1/MBNL1-mediated alternative splicing. First, RNA levels of CELF1-RNA stability targets were measured in brains from HD patients and mouse models, and those that were significantly different were verified by measuring mRNA decay in human and mouse neurons by 4sU-tagging. Next, we quantified the relative abundance of exons that are alternatively spliced by CELF1, MBNL1, or both in brains from HD patients and mouse models. Interestingly, reducing mutant Huntingtin levels in HD mice normalized expression of CELF1, MBNL1, and that of their respective target genes. Finally, to assess the physiological impact of increased CELF1 expression on HD pathogenesis, on going experiments aim to study the possible behavioural and histological benefits of reducing CELF1 expression in the striatum and cortex of the N171-82Q mouse model of HD.

Title: Disease-associated changes in huntingtin mRNA 3'UTR isoform abundance

Authors: ***L. ROMO**[1], E. PFISTER[1], A. ASHAR-PATEL[2], M. MOORE[2], N. ARONIN[1]; [1]Med., [2]Umass Med. Sch., Worcester, MA

Abstract: Huntington’s disease is a devastating neurodegenerative disorder caused by an expanded glutamine repeat within exon 1 of the huntingtin (HTT) gene. The wild-type and mutant allele are expressed as two alternatively polyadenylated mRNA isoforms with tissue-specific abundance. The isoforms differ only in the length of their 3′ untranslated region

(3′UTR), and both are processed into the HTT protein. Recent findings indicate mutant and wild-type mRNA exhibit different localization and stability. These differences may be due to alternative processing of mutant and wild-type mRNA into different isoforms. Here, we aimed to determine if the abundance of HTT 3′UTR isoforms changes in patient cells and brain tissue. Quantitative PCR assessed the abundance of the HTT long 3′UTR isoform mRNA in control and patient cortex and cerebellum, fibroblasts, and neural stem cells. We found patient cerebellum and motor cortex contain a higher abundance of long HTT isoform than controls. However, patient fibroblasts and neural stem cells contain a significantly lower abundance of long HTT isoform than controls. Allele-specific qPCR showed isoform changes originate from both the mutant and wild-type alleles. To determine if the isoform change was specific to HTT, we performed next generation polyadenylation (polyA) site sequencing on patient and control cerebellum and motor cortex. We found a previously unknown mid-3'UTR isoform of HTT, which is also conserved in mice. Of 4813 genes with two detected 3'UTR polyA sites in the cerebellum, only 6 exhibit significantly ($p<0.01$) different isoform ratios between patients and controls. In the motor cortex, 49 out of 5776 exhibit significantly different isoform ratios. Isoform shifts are likely not due to global or HTT-specific changes in gene expression. Disease-associated expression changes are opposite to HTT isoform changes: greater in the motor cortex (574/14194) than the cerebellum (12/13361). Additionally, HTT is not significantly differently expressed between patients and controls. These data indicate disease-associated changes in HTT isoform abundance are unique to HTT and unrelated to transcriptional changes.
Our studies reveal a new isoform of HTT mRNA and differences in HTT mRNA isoform abundance in patient brain and cell lines. Differences in HTT mRNA 3′UTR isoform abundance could explain different stability and localization of the mutant and wild-type allele. Also, the long 3′UTR may be the ideal target for small RNAs aiming to degrade mutant but not wild-type HTT mRNA in the brain.

Title: Recruitment of a transcriptional repressor to protein aggregates leads to de-repression of a pro-apoptotic gene activity and contributes to neuronal toxicity in polyglutamine diseases.

Authors: Z. S. CHEN[1], S. PENG[1], Q. ZHANG[1], D. D. RUDNICKI[2], *E. CHAN[1];

Abstract: Polyglutamine (polyQ) diseases are a growing group of dominant heritable neurodegenerative diseases caused by the expansion of glutamine-encoding CAG repeats located within the coding region of the affected genes. Expression of the mutant disease genes results in the biosynthesis of elongated polyQ disease proteins. Protein aggregate formation is a pathogenic hallmark of polyQ diseases. Polyglutamine aggregates recruit essential proteins in affected neurons, which leads to the cellular depletion of these aggregate-recruited proteins (ARPs) and results in perturbation of neuronal cell function. Transcriptional dysregulation caused by APRs has been reported in several polyQ diseases. Here, we demonstrate the sequestration of a transcriptional repressor protein to polyQ aggregates in the brain tissues of polyQ patients. We showed that the depletion of this repressor protein causes the transcriptional de-repression of a pro-apoptotic gene expression in cellular disease models and subsequently leads to neuronal apoptotic cell death. In summary, our investigation unveils a polyQ pathogenic pathway that involves a transcriptional repressor-triggered promotion of apoptotic cell death in polyQ disease. Targeting this novel pathway may be therapeutically beneficial.

Title: The implications of H3K9me3 in neuronal dysfunction underlying Huntington’s disease

Authors: *S. CHANDRASEKARAN[1], Y. JIANG[1], E. LOH[2], R. H. MYERS[3], L. SHEN[2], S. AKBARIAN[1];
[1]Psychiatry, [2]Neurosci., Icahn Sch. of Med. At Mount Sinai, New York, NY; [3]Neurol., Boston Univ., Boston, MA

Abstract: The human epigenome includes numerous histone post-translational modifications (PTMs) that confer varied chromatin states to modulate gene expression. As many PTMs are as-of-yet uncharacterized with respect to their roles in the brain, we began by exploring the involvement of one such mark -- the globally repressive histone 3 tri-methyl lysine 9 (H3K9me3) -- in cell-type-specific neuroepigenomic regulation in mouse cerebral cortex. Additionally, considering preliminary postmortem human data suggesting a pervasive 'derepression' differentiating Huntington's patients from controls, we sought to corroborate any H3K9me3-related findings from our mouse dataset in a postmortem brain cohort of Huntington's cases and controls. Nuclei from four wild type mouse cortices and four postmortem human tissue samples (Brodmann Area 9; two diseased, two age-matched controls) were sorted into neuronal and non-neuronal ("glial") populations using fluorescence-activated nuclei sorting. Following MNase digestion, chromatin immunoprecipitation with anti-H3K9me3 antibody was performed to isolate bound DNA fragments. Samples were ultimately submitted for high-throughput sequencing. Using BowTie2, retrieved sequencing files were aligned to the respective reference genomes (mm10 mouse, hg19 human); diffReps was used to annotate differential regions between the neuronal and glial subsets. Neuronal and glial H3K9me3 in the mouse ChIP-seq tracks showed significant differences in genome-wide distribution; further breakdown into genomic element categories revealed distinct patterns distinguishing the two populations, a majority of which occurred in "gene-poor" gene deserts and intergenic regions. Appreciable differences at these "gene-poor" regions in the neuronal and glial populations were also discernable between Huntington's and control samples. In sum, the above results about cell-type specific differences in H3K9me3 epigenomic profiles offer promising leads about the underlying importance of this PTM -- diseases with hallmarks of neuronal dysfunction could be closely linked with aberrant cell-type specific H3K9me3 landscapes. Ongoing work with rare asymptomatic Huntington's brains could further elucidate key neuroepigenetic determinants in this disease.

Title: Pias1 regulates mutant huntingtin accumulation and huntington's disease-associated phenotypes *In vivo*

Authors: *J. OCHABA[1], A. MAS MONTEYS[3], E. L. MOROZKO[1], J. G. O'ROURKE[4], J. C. REIDLING[2], J. S. STEFFAN[2], B. L. DAVIDSON[3,5], L. M. THOMPSON[2];

Med., The Univ. of Pennsylvania, Philadelphia, PA

Abstract: The disruption of protein quality control networks is central to pathology in Huntington's disease (HD) and other neurodegenerative disorders. The aberrant accumulation of insoluble high molecular weight protein complexes containing the huntingtin (HTT) protein and SUMOylated protein corresponds to disease manifestation. We previously identified a HTT selective E3 SUMO ligase, PIAS1, which regulates HTT accumulation and SUMO modification in cells. Here we investigated whether PIAS1 modulation in neurons alters HD-associated phenotypes *in vivo*. Instrastriatal injection of a PIAS1-directed miRNA significantly improved behavioral phenotypes in rapidly progressing mutant HTT (mHTT) fragment R6/2 mice. PIAS1 reduction prevented the accumulation and aggregation of mHTT, SUMO- and ubiquitin-modified proteins, increased synaptophysin levels, and normalized key inflammatory markers. In contrast, PIAS1 overexpression exacerbated mHTT-associated phenotypes and aberrant protein accumulation. These results confirm the association between aberrant accumulation of expanded polyglutamine-dependent insoluble protein species to pathogenesis and link phenotypic benefit to reduction of these species through PIAS1 modulation. Further, it suggests that PIAS1 may link protein homeostasis and neuroinflammation in HD through a combination of modulating or compensating for dysfunctional inflammatory signaling cascades between neurons and microglia, and modulating accumulation of toxic HMW species of HTT, potentially allowing improved homeostasis and flux through protein clearance pathways.

Title: Structural tissue changes and their effect on brain diffusion in the R6/2 mouse model of Huntington's disease

Authors: *L. VARGOVA[1,2], I. VORISEK[2], M. SYKA[2];
[1]Dept. of Neurosci., Charles University, 2nd Fac. of Med., Praha, Czech Republic; [2]Dept. of Neurosci., Inst. of Exptl. Med., Prague, Czech Republic

Abstract: Huntington's disease (HD) is a fatal human hereditary neurodegenerative disorder, caused by a mutation of the IT 15 gene. Selective degeneration of neurons and severe atrophy of the striatum result in progressive immobility, dementia and premature death. Magnetic resonance (MR) is often used to assess the progression of the disease. However, the MR results are more or less inconsistent, probably due to metalloprotein-bound iron accumulation in the striatum (1). To explore the background for MR changes in HD, we employed two different techniques to examine changes in the diffusion properties of the globus pallidus (GP) and the somatosensory cortex in the R6/2 mouse model of HD (HU) and in wild type controls (WT). The apparent diffusion coefficient of water (ADC_W) was determined by MR *in vivo*, while the extracellular space volume fraction α (α = extracellular volume/total tissue volume) and the tortuosity λ (λ^2 = free/apparent diffusion coefficient) were measured using the real-time iontophoretic (RTI) method *in situ*. In a potentially anisotropic globus pallidum, diffusion measurements were performed in the mediolateral (x), rostrocaudal (y) and ventrodorsal (z) axes. The results were correlated with histological analysis of the tissue.Diffusion in the GP was anisotropic, with preferential diffusion in the y axis in both WT and HU mice. Values of α were significantly lower in WT than in HU animals, while no significant difference was found in the values of tortuosity. Values of ADC_W in all axis were significantly higher in HU mice than in WT animals. Staining for chondroitinsulphate proteoglycan (CSPG) revealed a decrease in the relative fluorescent signal intensity by 28% in HU mice compared to control animals. At the same time, the number of NeuN positive neurons decreased to 73% of controls. Staining for GFAP reflects

astroglitic-like changes in astrocytes in the GP of HU mice. However, the ratio of GFAP-positive cells to the total cell count did not increase significantly. No significant differences between HU and WT animals in any of the studied parameters and variables were found in the cortex.Our results suggest that in the R6/2 model of HD, structural and diffusion changes are primarily expressed in the GP, not in the cortex. In the HU mice, a profound decrease in the number of neurons resulted in increased ADC_W and α values, while the expected decrease in tortousity λ due to enlarged α and loss of CSPG was prevented by an increase of diffusion barriers formed by the structural changes of astrocytes.

Title: Age-related changes in cortical and striatal NADPH-diaphorase staining in the Q175 mouse model of Huntington's disease.

Authors: *F. E. PADOVAN NETO, L. JURKOWSKI, C. MURRAY, A. WEST;
Neurosci., Rosalind Franklin Univ., North Chicago, IL

Abstract: In Huntington's disease (HD), corticostriatal and striatopallidal projection neurons preferentially degenerate as a result of mutant huntingtin expression and accumulation of polyglutamine inclusion bodies. Additional evidence points to abnormalities in striatal nitric oxide (NO) synthesis, cyclic nucleotide production, and phosphodiesterase expression which may be linked to deficits in corticostriatal transmission. The underlying mechanisms remain unknown, however, our recent studies in neuronal NO synthase (nNOS) knockout mice demonstrated that striatal projection neurons were substantially less responsive to cortical drive as compared to wild type (WT) controls, indicating that tonic NO acts to facilitate corticostriatal transmission in the intact striatum. Thus, deficits in corticostriatal transmission observed in HD could be associated with decreased nNOS activity in cortical-striatal circuits. Numerous labs have now shown that quantification of NADPH-diaphorase (NADPH-d) staining in striatum using optical density measures is an accurate index of nNOS activity. Because nitrergic interneurons are largely spared in the HD brain, we utilized NADPH-d histochemistry to assess

nNOS activity in male and female Q175 heterozygous mice (16 and 21 months of age). The impact of genotype and age was assessed in these animals using two-way ANOVA and Bonferroni post-hoc tests. In motor cortex, an overall effect of genotype on NADPH-d staining was observed between WT and Q175 het mice at 21 but not 16 months of age. Post-hoc comparisons revealed a significant decrease in NADPH-d staining at 21 months of age in male Q175, but not female mice as compared to WT controls. Also, an overall effect of genotype on striatal NADPH-d staining was observed between WT and Q175 mice at both 16 and 21 months of age. Post-hoc comparisons in 16 month old groups revealed no differences in NADPH-d staining across gender. Post-hoc comparisons in 21 month old groups revealed a trend towards a decrease in NADPH-d staining in males compared to WT controls, but no significant changes were detected in females. In summary, these data point to an age-dependent deficit in nNOS activity in the cortex and striatum in the Q175 mouse model of HD. Furthermore, males may be more susceptible to changes in nNOS activity in the cortex and striatum during aging. Taken together with previous studies, these observations indicate that decreased nitrergic transmission might contribute to circuit pathophysiology in HD, and that these deficits could be associated with disruptions in corticostriatal transmission observed in this devastating disease.

Abstract: Huntington’s disease (HD) is a fatal adult-onset neurodegenerative disease that results from expansion of a polyglutamine tract located at the amino terminus of the protein huntingtin

(htt). Consistent with the early deficits in synaptic and neuritic connectivity observed in HD, several independent studies documented deficits of fast axonal transport (FAT) in cellular and animal models of HD. However, a molecular basis for these deficits has not been established. Using the isolated squid axoplasm preparation, our prior work showed that pathogenic mutant htt (*mhtt*) inhibits FAT by promoting abnormal activation of c-Jun amino-terminal kinase 3 (JNK3). Further, these studies revealed that JNK3 directly phosphorylates kinesin-1 subunits of the motor protein conventional kinesin, inhibiting its microtubule-binding activity, but the relevance of these findings to mammalian neurons has not been established.
To evaluate the contribution of JNK3 to mhtt-induced deficits in FAT in a mammalian system, we generated R6/2-JNK3$^{-/-}$ mice. Remarkably, genetic ablation of JNK3 dramatically ameliorated R6/2 mice neuropathology and survival. Based on these observations, we performed an analysis of various FAT components in R6/2 and R6/2-JNK3$^{-/-}$ neurons. Collectively, the available data strongly suggests that JNK3-dependent alterations in the phosphorylation of major motor proteins responsible for FAT represent an important component of HD pathology.

Title: MID1-RNA interactions: implications in Huntington's disease.

Authors: *J. SCHILLING[1], A. DAGANE[2], I. ATANASSOV[3], E. WANKER[2], S. KRAUß[1]; [1]DZNE, Bonn, Germany; [2]Max Delbrueck Ctr., Berlin, Germany; [3]MPI for Biol. of Aging, Cologne, Germany

Abstract: Huntington’s disease (HD) is a hereditary neurodegenerative disorder leading to physical, mental and behavioral disabilities. The mutant gene product is characterized by an elongated stretch of CAG repeats in its first exon that transcribes into an extended sequence of polyglutamines within the Huntingtin (HTT) protein. This causes the protein to aggregate and to exert pathogenic effects on neurons. Additionally, mutant HTT RNA is known to be neurotoxic by itself. The mutation produces a stable hairpin in the transcript capable of enhancing translation in an *in vitro* reporter assay. Furthermore, this repeat-dependent translational induction is regulated by the MID1 protein complex. MID1 is a E3 ubiquitin ligase that affects translation initiation of multiple transcripts by interfering with mTOR and PP2A signaling. To

understand how the MID1 complex together with mutant HTT RNA is involved in the development of HD, we characterized their *in vitro* protein interactions by quantitative mass spectrometry. The two datasets show substantial overlap: 25% of the identified proteins are shared binding partners. These proteins are for example involved in RNA processing, splicing and translation. To shed light on their involvement in the pathophysiology we are characterizing common and unique candidates using *in vitro* and *in vivo* models of HD. Additionally, by mapping the MID1-RNA binding site we can study the binding mode of MID1 to HTT RNA. This could help to explain the mechanism underlying the translational induction of repeat RNA.

Abstract: The Hippo/YAP signaling pathway has been implicated in mammalian organ size regulation and tumor suppression. Specifically, this pathway plays a critical role in regulating the activity of the transcriptional co-activator Yes-associated protein (YAP), which modulates a proliferative transcriptional program by binding to the transcription factor TEAD. While the Hippo/YAP pathway is known to be inhibited during tumorigenesis, recent studies have revealed that it may also play a role in neurodegeneration. Specifically, while mammalian sterile 20 (STE20)-like kinase 1 (MST1), an upstream pro-apoptotic protein kinase in the Hippo pathway, reduces YAP activity and mediates oxidative stress-induced neuronal death, increases in YAP activity provide neuroprotection. Therefore, we investigated the possible role of this pathway in Huntington's disease (HD) pathogenesis. Our results demonstrate that there is a significant increase in phosphorylated MST1 (pMST1), the active form, in post-mortem human cortex from HD patients. Additionally, pMST1 was also increased in the striatum and cortex of $Hdh^{111/111}$ mice compared to control. There was also a significant and concomitant increase in

phosphorylated YAP, the inactive form, in HD post-mortem cortex as well as in $Hdh^{111/111}$ striatum. While YAP was expressed in both neurons and glia in post-mortem brain, YAP nuclear localization was decreased in HD compared to control cortex. Lastly, TEAD/YAP interactions were decreased in HD and there was a decrease in immunoprecipitated DNA following TEAD chromatin immunoprecipitation in HD brain, suggesting decreased transcriptional activity. Together, these results demonstrate that while MST1 is activated in HD nuclear YAP is decreased. Thus, Decreases in nuclear YAP and TEAD interactions could significantly contribute to the pathogenic mechanism in HD by altering gene expression.

Abstract: Huntington's disease is a genetic neurodegenerative disease caused by trinucleotide repeat (CAG) expansions in the HTT gene encoding the huntingtin protein with increased polyglutamine (polyQ) tract, causing motor dysfunction and cognitive deficits. Adult HD occurs in the range of ~38 to 50-55 repeats within the HTT gene, compared to the normal range of ~10-36 repeats. Moreover, juvenile HD patients with >60 repeats display very early age of onset in children. Numerous HD animal models from yeast to transgenic mice have investigated proteins interacting with mutant huntingtin to gain insight into the initial network of Htt interactions that may participate in HD. It will be of benefit to the field to analyze the entirety of Htt protein interaction data in the field (represented by more than ~250 published articles) to gain understanding of the breadth of possible protein interaction mechanisms initiated by mutant Htt compared to normal Htt, related to the HD disease process. For these reasons, this study

compiled Htt protein interaction observed in non-human animal models of yeast, Drosophila, mice, and related. Analyses includes ranges of HTT repeat numbers and Htt forms - full-length or fragments - investigated for defining Htt protein interactions. Systems biology analyses using Cytoscape defines functional categories of proteins interacting with Htt forms and proposes possible Htt protein interaction networks based on protein interaction database analyses. Htt protein interaction networks analyses illustrates the complexity of multiple neuronal functions involved including intracellular trafficking and transport, synaptic cell-cell communication and interactions, energy metabolism, cell viability, and gene/protein expression. Systems biology analyses among multiple HD models can together provide insight into mutant Htt protein interactions potentially involved in HD.

Title: Comparative study of HDL2 versus HD iPSC models

Abstract: Huntington’s Disease (HD) is a fatal autosomal dominant neurodegenerative disease caused by expanded CAG repeats in exon 1 of the *Huntingtin* (*HTT*) gene. Huntington disease-like 2 (HDL2), discovered and genetically defined by the Margolis group, is a rare, autosomal dominant neurodegenerative disorder, with remarkable clinical, genetic, and pathological similarities to HD. Neuropathology of both disorders is characterized by cortical and striatal degeneration and the presence of neuronal protein aggregates. HDL2 is caused by a CTG/CAG

expansion on chromosome 16q24. Normal alleles contain 6-28 triplets, while pathogenic repeats range from 40-59 triplets. In the CTG orientation, the repeat falls in the gene *junctophilin-3* (*JPH*3). Insight gained from HDL2 have facilitated the discovery of an antisense gene at the HD locus, the role of mutant HTT transcripts in HD neurotoxicity, and potential RNA processing deficits in HD. We have hypothesized that the HDL2 mutation leads to neurodegeneration via a combination of loss of *JPH3* expression, RNA toxicity of the sense strand transcript containing an expanded CUG repeat, and expression of polyglutamine from a cryptic gene on the antisense strand. To test this hypothesis we developed HDL2 iPSCs using the same non-integrating episomal method that we have used to generate HD iPSCs (HD iPSC Consortium, Cell Stem Cell, 2012). Here, we demonstrate that HDL2 iPSCs differentiate to neural phenotypes expressing markers of mature neurons. Neural progenitors derived from HDL2 iPSCs express wild-type and mutant *JPH3* message. HDL2 iPSCs differentiated to striatal neurons express less *JPH3* transcript than similarly differentiated control or HD iPSCs, consistent with studies of post-mortem HDL2 brain. Aggregation of *JPH3* transcripts into RNA foci was observed in differentiated HDL2 iPSCs, similar to the foci observed in HDL2 post-mortem brain. BDNF withdrawal increased death of differentiated HDL2 iPSCs compared to differentiated control iPSCs, quantitatively similar to the toxicity observed after BDNF withdrawal in differentiated HD iPSCs. As in HD iPSC cells, BDNF withdrawal-induced toxicity of differentiated HDL2 iPSCs was rescued by BDNF and by 7,8-dihydroxyflavone (*7,8-DHF*), a TrkB small molecule agonist. These results provide initial validation for our iPSC model of HDL2, and suggest the likelihood that HD and HDL2 share one or more pathogenic pathways. Identifying these common pathways may provide important leads in on-going efforts to find therapeutic targets in HD, HDL2 and, possibly, other neurodegenerative disorders.

Abstract: Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder cuased by an abnormal expansion of CAG repeats. It is presently unknown how the expanded CAG repeats cause degeneration, preferentially in striatal medium spiny GABA neurons. It has no effective treatment. The present proposal, building upon our successful establishment of iPSC lines from a cohort of HD families and our ability to differentiate human iPSCs to enriched populations of functional medium spiny GABA projection neurons, will attempt to uncover the cellular and molecular mechanisms underlying GABA neuron degeneration in HD. We revealed the pathological phenotypes of HD in GABA and other neuronal types that are derived from HD iPSCs in vitro. Our study will most likely build a human disease model for further mechanistic exploration and for drug discovery. It may also reveal potential mechanisms of preferential GABA neuronal degeneration caused by CAG reapeats.

Title: Inhibition of nonmuscle myosinIIB facilitates polyQ-aggregates and cellular toxicity in primary neurons and HD- iPSC-derived neurons

Authors: Y.-K. LEE[1], W.-K. JUNG[1], H.-E. CHOI[1], M.-H. JUN[1], Y. HUH[2], D.-J. JANG[3], *J.-A. LEE[4];
[1]HANNAM Univ., Daejeon, Korea, Republic of; [2]Korea basic science institute, Daejeon, Korea, Republic of; [3]Kyungpook Natl. Univ., Kyungpook, Korea, Republic of; [4]Hannam Univ., Dajeon, Korea, Republic of

Abstract: Huntington's disease (HD) whose symptoms are uncontrolled movements, emotional problems, and impairment of cognition caused by expansion and protein aggregates of a polyglutamine (poly-Q) repeat in the huntingtin protein. In the course of the disease, expanded

huntingtin accumulates as the heterogeneous forms of aggregates such as oligomers, fibrils, and large inclusion. However, how aggregation of polyQ-aggregates is regulated is largely unknown. In this study, we found that myosinIIB, a non-muscle-type of myosin as a molecular actin-based motor protein, was strikingly redistributed into large polyQ-aggregates in cells overexpressing EGFP-tagged N-terminal fragment of htt with 72 or 150 glutamine residues (Nhtt150Q-EGFP). Furthermore, we found that FUS and TDP-43 which are associated with frontotemporal dementia and amyotrophic lateral sclerosis was sequestered into polyQ-myosinIIB aggregates indicating their roles on cellular aggregation. To investigate the role of myosinIIB in poly-Q aggregation and cellular toxicity with blebbistatin, an inhibitor of myosinIIB, or myosinIIB siRNA was incubated in cells expressing Nhtt150Q-EGFP or Nhtt16Q-EGFP. Very interestingly, inhibition of myosinIIB by blebbistatin or siRNA facilitated accumulation of small size of soluble polyQ aggregates compared to control cells. Furthermore, inhibition of myosinIIB in Nhtt15OQ-expressing neurons enhanced cellular toxicity induced by the ER-stress in primary cortical neurons and HD-iPSC-derived neurons. Taken together, these data suggest that myosinIIB is involved in the process of formation of small poly-Q aggregates which is toxic to neurons under ER stress. Therefore, our study provides a novel role of myosinIIB as a regulator on poly-Q aggregation and ER-stress induced neuronal toxicity.

Title: Exacerbated SIRT3 activity alters mitochondrial function and dynamics in Huntington's disease models

Authors: *L. NAIA[1,2], C. CARMO[1], A. M. OLIVEIRA[1], J. VALERO[1,3], C. LOPES[1], C. R. OLIVEIRA[1,2], T. R. ROSENSTOCK[1,3], A. C. REGO[1,2];

Abstract: Huntington's disease (HD) is a genetic neurodegenerative disorder linked to expanded polyglutamine tract in the huntingtin (HTT) protein. Striatal medium spiny neurons are the most affected population. Although the mechanisms by which neurons die are uncertain, mitochondrial dysfunction has been implicated in HD pathogenesis. Rescue of mitochondrial morphology by modulation of mitochondrial dynamics could help to restore mitochondrial function. Therefore, we speculated that targeting SIRT3, a stress responsive NAD^+-dependent mitochondrial lysine deacetylase, might influence these processes. In the present work we show that ST*Hdh*$^{Q111/Q111}$ striatal cells, expressing mutant Htt with 111 glutamines, and HD patients-derived human lymphoblasts and induced pluripotent stem cells exhibited an increase in SIRT3 protein and mRNA levels, along with increased SIRT3 enzymatic activity, in comparison with control cells. Symptomatic YAC128 HD transgenic mice also presented increased SIRT3 mRNA levels and deacetylation of superoxide dismutase 2, a pre-recognized mitochondrial SIRT3 target. Concordantly, co-localization analysis revealed that HD striatal cells display an increased accumulation of overexpressed SIRT3 (SIRT3OE) in mitochondria, when compared to wild-type cells, as well as decreased lysine acetylation in both genotypes. Failure to maintain mitochondrial membrane potential (mmp) is one feature of HD striatal cells that has been linked with impaired balance in mitochondrial fission and fusion. Concordantly, untransfected HD cells displayed mitochondrial loss along with increased number of cells exhibiting a fragmented mitochondrial network. Remarkably, the unbalance between mitochondrial fission and fusion observed in HD cells was reduced after SIRT3OE, with higher prevalence of tubular mitochondria due to decreased accumulation of Fis1 and Drp1 in mitochondria. Preliminary data from single-cell functional imaging further revealed that SIRT3OE improves mmp in both wild-type and mutant striatal cells. Nevertheless, protein assessment of autophagy modulators revealed no significant changes following SIRT3OE. Overall, we report that increased SIRT3 activity ameliorates mitochondrial dynamics in HD striatal cells culminating in enhanced mitochondrial function and prevention of neuronal damage in HD.

Abstract: Rho kinases (ROCK) belong to the serine-threonine family and are involved in a variety of functions, axonal growth, synapse stability and migration. ROCK1 and 2 isoforms demonstrate high sequence similarity but differential tissue expression, with ROCK2 more prevalent in the CNS, and ROCK1 more abundant in peripheral organs. Abnormal activation of ROCK and downstream effectors has been reported in several CNS disorders, and it has been postulated that abnormal ROCK activation might play a role in the pathology of Huntington's disease. A number of ROCK inhibitors (ROCKi) exist including drugs such as fasudil and ripasudil for peripheral indications. Pharmacological ROCKi have been reported to have a benefit in neuronal degeneration, although no known ROCKi combine kinase selectivity with properties consistent with CNS exposure. We have developed a screening cascade designed to optimize compounds for ROCK biochemical and cellular potency, as well as monitor selectivity over the related kinases. Results from our lead compound, CHDI-00488367, demonstrate sustained brain exposure over the cellular IC50 following a single dose at 10 mg/kg. Samples from this study were profiled using KiNativ™ technology and showed that brain exposure correlated with target occupancy, giving us confidence that brain exposure would translate into an inhibition of ROCK activity at the intended site of action. These ROCKi have potential as tool compounds to assess whether they will reduce mHtt aggregation in an HD model system or have a positive impact on survival. Current efforts are targeted towards measurement of compound efficacy following *in vivo* dosing through a ROCK dependent mechanism. Efforts to develop an *ex vivo* biomarker to aid this approach will also be discussed.

Title: Potent, selective and brain penetrant ATM inhibitor suitable for a proof-of-concept study in HD models

Authors: O. LAZARI[1], P. BRECCIA[1], J. BATE[1], K. MATTHEWS[1], G. WISHART[1], H. VATER[1], S. L. MARTIN[1], H. COX[1], W. BLACKABY[1], G. MCALLISTER[1], D. YATES[1], *D. F. FISCHER[3], P. MILIANI DE MARVAL[2], L. TOLEDO-SHERMAN[4], R. CACHOPE[4], M. ROSE[4], I. MUNOZ-SANJUAN[4], C. DOMINGUEZ[4];
[1]Charles River, Saffron Walden, United Kingdom; [2]Charles River, Morrisville, NC; [3]Biofocus, Charles River, Leiden, Netherlands; [4]CHDI Foundation/Management Inc., Los Angeles, CA

Abstract: Emerging evidence shows that the Ataxia Telangiectasia Mutated kinase (ATM) signalling pathway is dysregulated in neurodegenerative disorders including Huntington's Disease (HD). ATM signalling has been shown to be elevated in cells derived from HD patients and mouse models of HD. Genetic and pharmacological evidence from cellular and animal models of HD suggests that reduction of ATM signalling can ameliorate mHTT toxicity. Thus an inhibitor of ATM kinase presents a promising therapeutic intervention strategy for the treatment of HD.We have developed a screening cascade designed to optimize compounds for ATM biochemical and cellular potency, as well as monitor selectivity over the related kinases ATR, DNA-PK and Vps34. Several promising series were identified, with appropriate properties for further studies. Results from our lead compound, CHDI-00485194, demonstrate sustained brain exposure over the cellular IC50 following a single dose at 100 mg/kg. Samples from this study were profiled using KiNativ™ technology and showed that brain exposure correlated with target occupancy, giving us confidence that brain exposure would translate into an inhibition of ATM activity at the intended site of action. These target engagement results were confirmed in a PK/PD biomarker study using WT mice dosed with the compound and challenged with 5 Gy of X-ray irradiation; here, a dose-dependent inhibition of radiation-induced phosphorylation of the ATM substrate, KAP1, was observed. Next steps are to move towards a full efficacy study with our lead compound in a HD mouse model.

Title: Therapeutic and disease-modifying effects of ganglioside GM1 in mouse models of Huntington's disease

Authors: ***M. ALPAUGH**, D. GALLEGUILLOS, L. C. MORALES, S. LACKEY, P. KAR, B. KERR, K. TODD, S. SIPIONE;
Univ. of Alberta, Edmonton, AB, Canada

Abstract: ***Background.*** Huntington disease (HD) is a neurodegenerative disorder caused by an expansion of a polyglutamine stretch in the huntingtin protein. The resulting mutant protein acquires toxic conformations and aggregates within the cells, leading to neuronal dysfunction and death. We previously showed that levels of ganglioside GM1, a lipid highly enriched in the brain, are decreased in HD models. Administration of exogenous GM1 resulted in normalization of motor behavior in a transgenic model of HD (YAC128 mice). These effects were accompanied by increased phosphorylation of mutant huntingtin at Ser13 and Ser16, a post-translational modification that was shown to decrease mutant huntingtin toxicity. **Objectives.** The aim of this study was to further characterize the therapeutic effects of GM1 and to demonstrate that GM1 is a disease-modifying treatment for HD. **Methods.** We measured motor and non-motor behaviour in three different models of HD (R6/2, YAC128 and Q140 mice) during chronic intraventricular infusion of GM1 or vehicle. At the end of the treatment, filter-trap assay, immunoblotting and stereology analysis were performed to determine whether GM1 affects neurodegeneration and levels of mutant huntingtin aggregates in treated mouse brains. **Results.** GM1 treatment decreased levels of soluble and insoluble huntingtin in HD mouse brains, and dramatically improved both motor and non motor symptoms of the disease. In R6/2 mice, GM1 attenuated striatal neuron and white matter loss, increased body weight and

prolonged survival. **Conclusions**. Our data suggest that GM1 has disease-modifying properties across HD mouse models and could therefore have therapeutic potential in HD patients.

Abstract: Huntington's disease (HD) is a lethal autosomal dominant neurodegenerative disorder resulting from a polyglutamine-encoding CAG expansion in the Huntingtin (*HTT*) gene. Targeting the Class IIa histone deacetylase HDAC4 appears to be a promising therapeutic strategy to treat HD. HDAC4 genetic reduction in the R6/2 HD mouse model ameliorated motor and CNS neurophysiological deficits and improved survival [1]. In addition, HDAC4 reduction delayed huntingtin (Htt) aggregation in CNS tissue from both the R6/2 and HdhQ150 full length KI mouse model of HD [1]. We have developed several chemical series of potent, selective, orally bioavailable and CNS-penetrant catalytic-site inhibitors of Class IIa HDACs [2,3], to probe whether HDAC4 inhibition can replicate the beneficial effects of HDAC4 reduction in HD models. This strategy is untested, as the deacetylase activity of Class IIa HDACs have been called into question [4]. Two structurally distinct lead series compounds have been evaluated in a battery of HD model interrogations, including R6/2 *in vivo* behavioral and survival endpoints and HD model *ex vivo* electrophysiological and molecular readouts following chronic dosing. These compounds; CHDI-00390576 and CHDI-00484077, differ as to the warhead used to engage the Zn^{2+} ion in the catalytic site of Class IIa HDACs (hydroxamate versus

trifluoromethyloxadiazole), their ability to disrupt HDAC4:HDAC3 associations, their pharmacokinetic (PK) and pharmacodynamic (PD) properties and their selectivity over Class I/IIb HDACs. We will present the detailed PK-PD biomarker and modeling approaches used to determine appropriate chronic dosing regimens for the inhibitors, and summarize our data where we determine that selective Class IIa catalytic site inhibition fails to replicate all beneficial effects seen following HDAC4 genetic reduction in HD models. While some neurophysiological deficits, restored following HDAC4 genetic reduction, are convincingly and dose-dependently restored in HD models following treatment with either compound; we failed to significantly impact behavioral deficits. We also had no effect on Htt aggregation levels through chronic dosing. Our results suggest that blocking the catalytic site of HDAC4 is insufficient to fully recapitulate the spectrum of biological functions that HDAC4 knock-down subserves in an HD context, whilst specifically improving some aspects of HD pathophysiology. 1] Mielcarek M., *et al.*, PLoS Biol, 2013. **11**(11): p. e1001717.[2] Burli R., *et al.*, J. Univ. of Ireland Galway, Galway, Ireland; [6]NCBES Galway Neurosci. Centre, Natl. Univ. of Ireland Galway, Galway, Ireland

Abstract: Huntington's disease (HD) is a fatal neurodegenerative disorder characterized by motor, cognitive and psychiatric symptomatology. Although motor features are the most evident cognitive deficits precede the overt motor symptoms by years in HD patients and are most highly associated with functional decline. Several studies have reported transcriptional dysregulation as an early underlying pathogenic mechanism in HD. Accordingly, therapeutic development has focused on targeting Histone deacetylases (HDACs) with small-molecule inhibitors in order to increase histone acetylation and raise gene transcription. However, the benefits of broad-based inhibitors in HD pathology could be counteracted by their potential toxicity, especially in chronic treatments. In this regard, Histone deacetylase 3 (HDAC3) has been implicated in HD mice as enforcing transcriptional aberrations and helps fuel expansions of CAG repeats in cultured cells. Importantly, it has also been reported that HDAC3 plays a critical role in memory formation.
In view of that, we have investigated whether RGFP966, an isotype-selective inhibitor of HDAC3, improves cognitive deficits and somatic CAG expansions in the $Hdh^{Q7/Q111}$ knock-in (KI) mouse model of HD. Behavioral assessment revealed that early chronic treatment with RGFP966 completely reversed altered motor learning and impaired recognition and spatial memories in KI mice. Biochemical and genetic analysis in mouse brain samples showed that systemic administration of RGFP966 normalized the expression of memory-related genes, partially recovered striatal pathological markers and decreased aggregation of mutant huntingtin. Using molecular biology techniques to assess expansion frequencies, we could detect that chronic treatment with RGFP966 also suppressed striatal CAG repeat expansions.
Taken together, our results reveal a good pharmacotherapeutic approach to prevent HD cognitive decline and, simultaneously, to suppress somatic CAG repeat expansions that drive disease progression.

Abstract: Corticostriatal atrophy is a cardinal manifestation of Huntington's disease (HD). However, the mechanism(s) by which mutant Htt protein (mHtt) contributes to the degeneration of the corticostriatal circuits in HD is not completely understood. Herein, we investigated the mechanisms by which individual subunit of TRiC (TCP-1 Ring Complex or CCT) impacted the level of mHtt and striatal atrophy in HD. By recreating the corticostriatal neuronal circuit in microfluidic chambers using neurons from BACHD mice, we have demonstrated that CCT3 or purified apical domain of CCT1 (ApiCCT1) normalized BDNF transport from cortical to striatal neurons and rescued striatal neuronal atrophy in BACHD. CCT3 and ApiCCT1 also restored retrograde axonal transport of BDNF as well as lysosomal transport in cortical neurons. Further, both CCT3 and ApiCCT1 decreased the level of mHtt in BACHD cortical neurons and, in 14A2.6 cells. Our findings suggest that TRiC reagents promote selective degradation of mHtt to enhance supplies of cortical BDNF to striatal neurons.

Title: An efficient antibiotic inducible gene therapy system for Huntington's Disease neurons

Authors: *A. KOMARLA[1,2], P. DENG[2,1], A. TORREST[2], J. APRILE[2], W. CARY[2], J. GUTIERREZ[2], W. GRUENLOH[2], G. ANNETT[2], T. TEMPKIN[3], V. WHEELOCK[3], D. J. SEGAL[1], J. NOLTA[2], K. FINK[2];

Syst., [3]Dept. of Neurology, Univ. of California Davis Hlth. Systems, Univ. of California, Davis, Sacramento, CA

Abstract: Huntington's disease (HD) is a genetic neurodegenerative disease that is caused by the abnormal expansion of the CAG repeats region the HTT gene on exon 1 of chromosome 4 that normally encodes for the huntingtin protein, known to facilitate neuron growth and maintenance. Accumulation of mutant huntingtin is toxic to neurons and causes the activation of pro-apoptotic molecules, eventually resulting in neuronal death. Selective loss of striatal neurons early in the disease results in symptoms such as chorea, cognitive and emotional disturbances and other forms of motor dysfunction.
Our lab uses Transcription Activator-Like Effectors (TALEs) partnered with Krüppel associated box (KRAB) domain to target Single Nucleotide Polymorphisms (SNPs) in mutant allele and cause selective transcriptional repression. Following delivery of TALEs into HD fibroblasts

using conventional transfection methods, we observed robust silencing of the mutant gene and subsequent reduction in mutant protein. However, transfection efficacy was limited but highly correlated to gene repression underlying the need for an optimized delivery platform.
The present study focused on a viral delivery method to increase transfection efficiency in combination with an antibiotic inducible system to allow regulated expression of the TALE-KRAB complex. We chose a TALE that demonstrated specific allele repression and targets a SNP that exists in a transgenic mouse model to clone into our Tet-On inducible lenti-TALE system (TTS). T3γ-KRAB was cloned into an inducible lentivirus with an eGFP reporter plasmid and the presence of the fluorescent reporter was analyzed using flow cytometry. We then tested the TTS in both primary fibroblasts isolated from HD patients and in primary neurons isolated from the YAC128 mouse model. Our primary outcome measures were the reduction of the mutant allele using SNP-genotyping and reduction of mutant huntingtin protein using Western Blot. This study will allow testing of a viral delivery method in partnership with an antibiotic inducible system that can provide useful information on future gene therapy delivery methods.

Title: Behavioral and electrophysiological improvements following up-regulation of glt1 in the q175 Huntington’s mouse model

Authors: ***K. D. BUNNER**, C. RANGEL-BARAJAS, B. M. MCCORMICK, S. J. BARTON, G. V. REBEC;
Program in Neurosci. & Dept. Psychological & Brain Sci., Indiana Univ., Bloomington, IN

Abstract: Huntington’s disease (HD) is an inherited neurodegenerative condition that typically strikes in mid-life with progressively deteriorating cognitive, emotional, and motor symptoms. While the sole cause of HD, a CAG repeat expansion on the short arm of chromosome 4, is known, currently no effective treatment or means to slow the progression of this disorder exists. Previous work by our group has shown electrophysiological and behavioral changes in the Q175

mouse that parallels changes seen in other HD mouse models. We found a significant decrease in quality of nest built and percentage of Nestlet used in both heterozygous (HET) and homozygous (HOM) Q175s compared to wild-type (WT) controls. Q175 mice also show a significant decrease in number of line crossings compared to WT mice along with changes in spontaneous behaviors (i.e. grooming, quiet rest, and rearing). In striatum, electrophysiological changes, including increased spike rate in HETs accompanied by a significant decrease in patterns of burst firing relative to WTs, suggest an early vulnerability to HD. Here, in light of inadequate glutamate uptake in both HD patients and mouse models, we increased expression of GLT1, the protein responsible for >90% of glutamate uptake, by viral-mediated gene transfer. Intravascular administration of adeno-associated virus serotype 9 (AAV9), which crosses the blood-brain barrier, was used to up-regulate GLT1. We assessed behavioral and striatal neuronal changes beginning at >6 weeks after AAV9-GLT1 injection. Although our data analysis is ongoing, we find that HET mice show patterns of both nest building and striatal neuronal activity that now parallel those of WT controls. Thus, our results, even at a relatively early stage of data analysis, support evidence for GLT1 as a therapeutic target for reversing the behavioral and neuronal deficits in HD.

Title: Effect of GLT-1 up-regulation on striatal local field potential activity and motor performance

Authors: *C. RANGEL BARAJAS, K. D. BUNNER, S. J. BARTON, G. V. REBEC; Psychological and Brain Sciences, Program in Neurosciences, Indiana Univ., Bloomington, IN

Abstract: Dysregulated glutamate transmission plays a key role in Huntington’s disease (HD), a dominantly inherited neurodegenerative condition caused by an expanded CAG repeat (Q) in the gene that encodes for the huntingtin protein (HTT). HD is characterized by progressively worsening cognitive, psychiatric, and motor symptoms. Although the search for an effective therapeutic target continues, it is noteworthy that HD patients as well as transgenic mouse

models of HD show a down-regulation of the glutamate transporter-1 (EAAT2 in humans and GLT1 in rodents). Here, we used the adeno-associated virus serotype-9 (AAV9) to induce viral-mediated gene transfer to increase GLT1 expression in the Q175 knock-in (KI) mouse model. We assessed rotarod performance in heterozygous (HET) and homozygous (HOM) Q175s as well as wild-type (WT) controls from ≈32-60 weeks of age. Striatal local field potential activity (LFP) was recorded from the same animals as they entered the choice point or center of a plus-shaped maze. The intravascular administration (0.1 ml, [$1x10^{13}$ vg/ml]) of AAV9-EAAT2 administered around ≈24 weeks of age, elevated the GLT1 expression in striatum, and significantly improved rotarod performance progressively by increasing the latency to fall at with a maximum performance at 50 weeks of age when compared with untreated mice (22.83 ± 4.6 s vs 43.05 ± 2.6 s), no significant effect was found in either wild type (WT) or homozygous (HOM) mice at the same age. In the plus-maze, the total number of arm choices was significantly increased in WT and HET especially at older ages (≈48 weeks of age), while in HOM mice the effect was mainly in the early stages (≈32-40 weeks of age). Although the turning probability in the plus maze was not affected by AAV9-EAAT2 treatment, the striatal LFP power spectral density for delta wavelength after the choice point on the maze, was increased in HET mice compared to untreated mice, while in HOM mice, the increased delta power observed in untreated mice was ameliorated by AAV9-EAAT2 administration. These data suggest that the increased expression of EAAT2 in might be a potential therapeutic treatment for the motor alterations observed in HD.

Title: Molecular mechanism underlying defective BDNF secretion from astrocytes expressingmutant huntingtin

Authors: *Y. HONG, T. ZHAO, X.-J. LI, S. LI;
Human Genet., Emory Univ., Atlanta, GA

Abstract: Huntington's disease (HD) is a fatal, inherited, neurodegenerative disorder that affects one in every 10,000 Americans. However, there is no effective treatment for HD to date, in part because the pathogenic mechanism driving the disease is incompletely understood. A mutant form of the huntingtin protein (htt), in which a polyQ repeat region is greatly expanded, is a critical molecular feature of the disease. The huntingtin protein is necessary for multiple cellular functions, including gene transcription and vesicle trafficking. However, mutant htt is toxic to neurons. Most studies of neurodegenerative diseases have been focused on neurons because degeneration is observed mainly in neuronal cells. However, the survival of neuronal cells is also supported by glial cells such as astrocytes. One important role of astrocytes is to synthesize and release brain-derived neurotrophic factor (BDNF), which is vital for neuronal survival, development and function. Mutant htt is found in astrocytes both in the brains of HD patients and mouse models of the disease; however, little is known about the pathogenic role of mutant htt in astrocytes. In this study, we used a HD140Q knock-in mouse model and a transgenic HD mouse model (GFAP-160Q) that specifically expresses N-terminal mutant htt in astrocytes to study the effect of mutant htt on BDNF secretion. Our results indicate that compromised exocytosis of BDNF in HD astrocytes contributes to the decreased BDNF levels in HD brains and underscores the importance of improving glial function in the treatment of HD.

Title: Immunoprecipitation and flow cytometry huntingtin lowering biomarkers

Authors: ***A. L. SOUTHWELL**[1], N. S. CARON[1], S. E. P. SMITH[2], Y. XIE[1], J. SONG[3], I. SEONG[4], B. R. LEAVITT[1], M. R. HAYDEN[1];

Abstract: Huntington disease (HD) is a progressive neurodegenerative disorder caused by expansion of a polyglutamine encoding CAG trinucleotide repeat in the gene encoding the huntingtin protein (HTT). Although age of onset in HD can be predicted based on CAG repeat

length, this variable accounts for only 50-70% of the variation, while multiple known and unknown genetic and environmental factors account for the remainder. Thus, there is a need for biomarkers that could more accurately predict disease conversion or progression. Levels of mutant HTT protein or of specific species of mutant HTT protein in the brain could be such biomarkers. Additionally, there are multiple HTT lowering therapeutics in preclinical and clinical development, for which quantification of HTT levels in the brain is essential to validate and quantify target engagement. It is not currently possible to directly quantify HTT levels in the living brain of patients. To overcome this, we have developed an ultrasensitive mutant HTT detection method, micro-bead based immunoprecipitation and flow cytometry (IP-FCM), suitable for use in HD patient and model mouse cerebrospinal fluid (CSF). We have used IP-FCM to demonstrate that mutant HTT protein is elevated after disease onset in CSF from HD mutation carriers and that CSF mutant HTT level correlates to multiple clinical measures, including motor and cognitive performance. Using HD model mice, we have demonstrated that the brain is the major source of mutant HTT protein in CSF and that CSF mutant HTT protein levels reflect brain levels, decreasing following CNS HTT lowering intervention. Thus, mutant HTT IP-FCM has potential applications as a biomarker of HD onset/progression and as a target engagement and pharmacodynamic biomarker of HTT lowering therapies. In ongoing work we are using an allelic series of recombinant full-length huntingtin proteins (Q2, Q23, Q43, Q67, Q78) to further characterize mutant HTT IP-FCM. This will allow for more accurate comparison between individuals and for absolute protein quantitation. Additionally, we are continuing development of IP-FCM assays with different specificities, such as total HTT protein and cleaved HTT protein. These companion assays could be used in conjunction with mutant HTT IP-FCM to evaluate allelic effects of HTT lowering therapies or to investigate proteolytic processing of mutant HTT, respectively. These assays could provide essential clinical diagnostics and valuable research tools for studies of the pathogenesis of HD.

Title: Proteasome activator, PA28γ, improves motor coordination and proteasome function in Huntington's disease YAC128 mice

Authors: *J. JANG[1], J. JEON[1], W. KIM[1], O. ISACSON[2], H. SEO[1];
[1]Hanyang Univ., Ansan, Korea, Republic of; [2]Neurodegeneration Inst., McLean Hospital, Harvard Med. Sch., Belmont, MA

Abstract: Huntington's disease (HD) is an autosomal dominant neurological disorder with progressive degeneration of medium sized spiny neurons (MSN) in the caudate putamen area. Previous studies showed the inhibited proteolytic activities of the ubiquitin–proteasome system (UPS) in HD patient's brain. It has been reported that proteasome activator (PA), PA28γ enhanced proteasome activities and cell survival in *in vitro* HD model. In this study, we found whether PA28γ gene transfer improves the proteasome activities and pathological symptoms in *in vivo* HD model. We stereotaxically injected lenti-PA28γ virus into the striatum of mutant YAC128 HD mice and littermate controls at 14–18 months of age, and validated their behavioral and biochemical changes at 12 weeks after the injection. YAC128 mice showed a significant increase in their peptidyl-glutamyl preferring hydrolytic (PGPH) proteasome activity and the mRNA or protein levels of brain derived neurotrophic factor (BDNF) and pro-BDNF after lenti-PA28γ injection. The number of ubiquitin-positive inclusion bodies was reduced in the striatum of YAC128 mice after lenti-PA28γ injection. YAC128 mice showed significant improvement of latency to fall on the rota-rod test after lenti-PA28γ injection. These data demonstrate that the gene therapy with PA28γ can improve UPS function as well as behavioral abnormalities in HD model mice.

Title: Bexarotene activation of PPAR-delta ameliorates preclinical trial outcomes in Huntington's Disease by promoting mitochondria metabolic function and autophagy

Authors: ***A. S. DICKEY**[1], D. SANCHEZ[1], N. LOMAS[1], K. R. SAMPAT[1], A. FLORES[1], W. FAN[2], N. ARBEZ[3], C. A. ROSS[3], R. M. EVANS[2], E. MASLIAH[1], A. R. LA SPADA[1]; [1]Sanford Consortium - UCSD, La Jolla, CA; [2]Salk Inst., La Jolla, CA; [3]Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Huntington's disease (HD) is a relentlessly progressive autosomal dominant neurodegenerative disorder characterized by involuntary movements, cognitive decline, and psychiatric illness. Studies by our group and others have shown that mitochondrial dysfunction and metabolic deficits in HD result from transcriptional dysregulation of peroxisome proliferator-activated receptor [PPAR] gamma coactivator-1 alpha (PGC-1α). As a transcriptional regulator, PGC-1α modulates nuclear receptor transcription factors including PPARδ, the most abundantly expressed subtype in CNS. We recently reported that repression of PPARδ transactivation contributes to HD pathogenesis, and demonstrated in a rigorous preclinical trial that treatment of HD mice with the PPARδ agonist KD3010 is an effective therapy, significantly ameliorating motor phenotypes, markedly reducing striatal neurodegeneration, and greatly extending lifespan.

Another aspect of PPARδ biology with relevance for therapy development is that PPARδ forms a heterodimer with the retinoid X receptor (RXR), with availability of RXR as a limiting factor for PPARδ activity, so RXR agonists are capable of promoting PPARδ transactivation. One compound with potent RXR agonist activity is bexarotene, a synthetic compound structurally similar to retinoic acid, which upon administration to AD mice yielded dramatic improvements in behavioral deficits and enhanced clearance of Aβ oligomers. We tested if PPARδ activation may contribute to bexarotene neuroprotection in cell culture and primary neuron models of HD. Our findings indicate that bexarotene neuroprotection against htt protein neurotoxicity depends upon engagement with PPARδ.

To determine if bexarotene is a therapy candidate for HD, we performed a preclinical trial of bexarotene in HD N171-82Q mice, and documented significant improvements in motor phenotypes and neuropathology. We examined the mechanistic basis for PPARδ agonist neuroprotection by evaluating metabolic function in primary neurons from BAC-HD mice treated with KD3010 or bexarotene, and observed a dramatic rescue of impaired oxygen consumption, oxidative phosphorylation, and glycolytic activity upon KD3010 or bexarotene treatment. Also, these agonists rescued mitochondrial fragmentation, and increased autophagy. Our results provide strong support for PPARδ agonist therapy as a treatment for HD, uncover improved mitochondrial metabolic function as a central feature of PPARδ agonist neuroprotection, and highlight the PGC-1α - PPARδ pathway as an attractive therapy target for HD and related neurodegenerative disorders characterized by mitochondrial dysfunction.

Title: Decreased of HSP 70, XIAP, ikbα, it15 genes expression and the CAG repeat expansion of animals treated with rnai in an experimental model of huntington's disease

Authors: *R. AVILES REYES[1], G. SARMIENTO[1], P. PALACIOS[2], S. ANDRADE[2];
[1]Univ. of Guayquil, Guayaquil, Ecuador; [2]Pontifical Catholic Univ., Quito, Ecuador

Abstract: The aggregation of the huntingtin protein (Htt) induces a progressive neurodegenerative disorder called Hunting Diease (HD). This pathology have an autosomal dominant inheritance. This neuropathology causes mutation of CAG trinucleotide repeat expansion. The CAG repeat is translated into a polyQ stretch. In this study we inoculated quinolinic acid (QA) intra cerebrally (Atlas of Paxinos and Watson, 1986: AP = +1.2 ahead of Bregma, L = +2.8 and DV = -5.5). Incisor bar location to 2 mm below the interaural line), to wistar rats in an experimental model of Huntington Disease. In the experimental design we worked with animal's treatment as: control; QA; QA+SS; QA+RNAi. In addition we analyzed HSP70, XIAP, IkBa, IT15 genes by RT-PCR. The sequencing technique was did only for IT15 gene. The result obtained of this research were found over expression of the genes analyzed. In the sequencing study we showed that the animals with RNAi had lower CAG repeat expansion. The results obtained evidenced a significantly RNAm expression in the QA and QA+SS animals, contrary that occurs in the animals with RNAi. It could support that: if we use an interference it could detain in some grade the fast progression of Huntington disease.

Title: Functional brain reorganization after exercise training in the CAG140 knock-in mouse model of Huntington's disease

Authors: *D. P. HOLSCHNEIDER[1], Z. WANG[1], D. P. STEFANKO[2], W. A. TOY[2], Y. GUO[1], G. M. PETZINGER[2], M. W. JAKOWEC[2];
[1]Psychiatry & the Behavioral Sci., [2]Neurol., USC, Los Angeles, CA

Abstract: We recently reported genotypic differences in resting state cerebral perfusion in a Huntington's Disease (HD) mouse model characterized by a gene knock-in (KI) of a human exon 1 CAG140 expansion repeat (CAG140 KI mice). CAG140 KI animals showed significant hypoperfusion of the basal ganglia motor circuit, hyperperfusion of cerebellar-thalamic and somatosensory regions. These genotypic differences were noted in male mice at 6 months of age prior to the manifestation of motor deficits. We now report the effects daily treadmill exercise has on resting state perfusion maps following 5 months of daily treadmill training. Regional cerebral blood flow (rCBF) was mapped at rest in awake, nonrestrained, male, 6-month old CAG140 KI and wild-type (WT) mice using 14C-iodoantipyrine autoradiography. Results were analyzed in three-dimensionally reconstructed brains by statistical parametric mapping. Exercised compared to sedentary CAG140 KI mice showed an increase in rCBF of the dorsolateral striatum and posterior motor cortex (M1, M2), whereas exercise in WT mice demonstrated a decrease in rCBF. Exercised CAG140 KI mice compared to exercised WT animals showed increased rCBF in the cerebellum, the ventrolateral thalamus and posterior-most motorsensory cortex, suggesting a greater engagement of the cerebellar-thalamocortical pathway. Our results suggest that exercise elicits a functional reorganization of whole-brain networks at a presymptomatic stage in the life of the CAG140 KI mouse.

Title: Pharmacological elevation of 2-arachidonoylglycerol brain levels rescues motivational dysfunction and accumbal correlates in a Q175 mouse model of Huntington's disease

Authors: *H. M. DANTRASSY[1], D. P. COVEY[1], N. E. ZLEBNIK[1], H. QADIR[1], E. COLE[1], M. A. ANAYA[1], I. GILDISH[1], J. F. CHEER[1,2];
[1]Anat. and Neurobio., [2]Psychiatry, Univ. of Maryland Sch. of Med., Baltimore, MD

Abstract: Huntington's disease (HD) is an inherited neurodegenerative disorder caused by a polyglutamine (CAG) expansion in the huntingtin gene. Striatal and cortical dysfunction are the hallmark neuropathological features underlying dyskinesia (e.g., chorea) and akinesia at later stages. However, prominent psychiatric symptoms manifest prior to motor dysfunction. We have recently shown in the Q175 mouse model of HD that suppressed motivation - one of the earliest indicators of HD - is associated with compromised dopaminergic signaling and network dynamics in the nucleus accumbens (NAc). Because NAc functioning and motivation are tightly regulated by cannabinoid type 1 receptor (CB1R) function, and CB1R expression and function are disrupted in HD, we assessed CB1R regulation of NAc activity and motivation. To characterize this relationship, *in vivo* electrochemical and electrophysiological recordings were collected in the NAc of wild type (WT) and Q175 knock-in mice. Separate groups of animals were chronically implanted with carbon fiber microelectrodes to measure subsecond dopamine release or multi-electrode arrays to record extracellular local field potentials and single-unit cell firing. Recordings were obtained during a progressive ratio (PR) schedule of reinforcement following treatment with the monoacylglycerol lipase inhibitor JZL-184 and the CB1R inverse agonist AM-251. Relative to WT controls, raising tissue levels of the endocannabinoid (eCB) 2-arachidonoylglycerol (2-AG) in HD mice rescues deficits in NAc dopaminergic and single-unit encoding of reward, attenuates abnormal gamma power and ameliorates motivational deficits. Our findings indicate that modulating NAc abnormalities with eCB-based therapies may be beneficial in treating the prodromal psychiatric deficits in HD.

Abstract: Epidemiological studies support that physical activity plays an important role in providing protection fromthe neurorehabilitation of a number of neurological disorders, including Parkinson's disease, Alzheimer's disease, and age-related cognitive impairment. In animal models of these disorders, physical activity in the form of exercise (treadmill running) can restore both motor and cognitive behavioral deficits and modify disease progression. While some studies have begun to address the role of physical activity in rodent models of Huntington's disease (HD) we Our laboratory has been are interested in exploring the impact of exercise as a long-term component of lifestyle in a model of Huntington's disease (HD)HD with a long prodromal period. For these studies, we subjected CAG_{140} knock-in mice to running on a motorized treadmill starting at 1 month of age, 3 days per week for 1 hour, and continuing for 1 year. This line demonstrates a long prodromal period and does not display HD-like motor symptoms until after 12 months of age. However, starting at 4 months of age, HD mice displayed cognitive deficits and depression-like behaviors, as well as the formation of aggregates of the mutant huntingtin mHtt protein (mHtt)aggregates. We found that exercise alleviates alleviated non-motorcognitive deficits and depressive behaviors and significantly reduces reduced HD pathology. We also examined the impact of exercise on dendritic spine density and expression of proteins involved in synaptic integrity, which are were altered by exercise in this model. At 12 months of age, with continuing exercise, there is was a delay in the onset of motor symptoms in HD mice compared to sedentary mice. To better understand the relationship between exercise and its neural substrates, we have begun to explore functional brain mapping changes with perfusion autoradiography using the tracer [^{14}C]-iodoantipyrine. Interestingly, sedentary CAG_{140} KI mice at 6 months of age showed hypo-perfusion of the basal ganglia circuit and hyper-

perfusion of several regions, including cerebellar-thalamic and somatosensory regions, indicating significant early cerebral functional re-organization in this model. Taken together, these studies begin to demonstrate that long-term changes in lifestyle, including physical activity has ave significant impact on brain health and may offer insight into mechanisms that may serve as targets in discovering novel therapeutic modalities to treat brain disorders such as HD.

Title: L-theanine, a component of green tea spares striatal neurons from 3-NP induced neurotoxicity: Role of Nitric Oxide pathway

Authors: *S. JAMWAL, JR, P. KUMAR;
Pharmacol., ISF Col. of Pharmacy, Moga, Moga, India

Abstract: Aim and Background: L-theanine is unique amino acid which readily crosses blood brain barrier and posses neuroprotective potential against neurodegenerative disorders including Huntington Disease (HD). HD is characterized by selective loss of GABAergic medium spiny neurons. Therefore, the present study was intended to investigate the effect of L-theanine against 3-NP induced striatal toxicity. **Methods:** Rats were administered with 3-NP for 21 days. L-theanine was given once a day, 1 hour prior to 3-NP treatment for 21 days and L-NAME (NOS inhibitor) and L-arginine (NOS activator) were administered 1 hour prior to L-theanine treatment. Body weight, behavioral parameters (locomotor activity, grip strength, narrow beam walk) observation was done on weekly basis up to 3 weeks after 3-NP treatment. On 22^{nd} day, animals were sacrificed and rat striatum was isolated for biochemical (mitochondrial complex-II, LPO, GSH and nitrite), pro-inflammatory cytokines (TNF-α, IL-6 and IL-1β) and neurochemical analysis (GABA, Glutamate, DA, NE, 5-HT, DOPAC, HVA, 5-HIAA and Adenosine). **Results:** 3-NP treatment significantly altered body weight, locomotor activity, motor coordination, mitochondrial complex-II activity, oxidative defence, pro-inflammatory mediators (TNF-α, IL-6 and IL-1β), and striatal neurotransmitters level i.e. GABA, glutamate, catecholamines, adenosine, inosine and hypoxanthine whereas L-theanine treatment (25 & 50

mg/kg/day, p.o.) significantly prevented these alterations. Concurrent treatment of L-NAME with L-theanine (25 mg/kg/day, p.o.) significantly enhanced protective effect of L-theanine (25 mg/kg/day, p.o.) whereas concurrent treatment of L-arginine with L-theanine (50 mg/kg/day, p.o.) significantly decreased the protective effect of L-theanine (50 mg/kg/day, p.o.). **Conclusion:** The neuroprotective potential of L-theanine involves inhibition of detrimental nitric oxide production and prevention of neurotransmitters alteration in striatum.

Title: Effect of amyloid precursor protein knock-down in the YAC128 mouse model of Huntington's disease.

Authors: K. L. BERGGREN[1], S. AGRAWAL[1], J. A. FOX[1], R. NELSON[2], *J. H. FOX[1]; [1]Vet. Sci., [2]Zoology-Physiology, Univ. of Wyoming, Laramie, WY

Abstract: Huntington's disease (HD) is an autosomal dominant disorder caused by a CAG expansion in the *HTT* gene. Elevated brain iron in susceptible brain regions is a consistent feature of murine and human HD. Amyloid precursor protein (APP) is implicated in neuronal iron export and levels are decreased in the R6/2 mouse HD model. Here we tested the effect of genetic knock down of APP on disease progression in YAC128 mice. APP hemizygous mice ($APP^{+/-}$) were crossed with YAC128 transgenic HD mice to generate $APP^{+/+}$ $HD^{+/-}$, $APP^{+/-}$ $HD^{+/-}$, $APP^{+/+}$ $HD^{-/-}$ and $APP^{+/-}$ $HD^{-/-}$ mice. Behavioral, brain biochemical and morphometric outcomes were determined. Mutant huntingtin protein (mhtt) expression resulted in an age-dependent decrease in rota-rod motor endurance. $APP^{+/-}$ mice also had decreased motor endurance as compared to $APP^{+/+}$ mice. Nest building behavior over a 24-hour period was also assessed. Both HD and $APP^{+/-}$ mice had significantly lower nest building scores and there was also a significant HD x APP interaction (p=0.0065). Stereologic analysis at 12-months of age revealed that YAC128 HD mice had smaller striatal volumes and fewer striatal neurons (p=0.0424) but there was no effect of APP genotype. Both cortical and striatal iron levels were significantly increased in $APP^{+/-}$ $HD^{+/-}$ as compared to $APP^{+/+}$ $HD^{+/-}$ mice (p-values=0.0155 and 0.0202, respectively); however, there were no effects of APP knock down on striatal and cortical iron levels in wild-

type mice. The findings indicate that YAC128 mice are more sensitive to the effects of genetically decreased APP on brain iron as compared to wild-type mice. APP knockdown potentiates some markers of HD progression.

Title: Therapeutic delivery strategies for the apical domain of CCT1 in Huntington's disease.

Authors: *J. OVERMAN[1,2], Z. CROOK[3], Z. TAN[2], A. LAU[2], L. JOACHIMIAK[4], E. SONTAG[4], A. TOMLINSON[4], J. REIDLING[2], B. DEVERMAN[5], C. GLABE[2], J. FRYDMAN[4], D. HOUSMAN[3], L. THOMPSON[2];

Abstract: Huntington’s disease (HD) is associated wtih aggregation of misfolded mutant Huntingtin (mHTT), ultimately resulting in intranuclear and cytoplasmic inclusions within neurons and neurite processes. While the precise role of aggregation in HD is not clear, protein misfolding and the aggregation process appears relevant to aberrant mHTT accumulation. The chaperone protein CCT (chaperonin containing TCP-1/TCP-1 ring) binds and folds proteins during *de novo* protein synthesis. Our previous work demonstrated that exogenous delivery of the substrate-binding apical domain of subunit 1 of CCT (ApiCCT1) is sufficient to decrease mHTT aggregation and rescue mHTT-mediated toxicity in multiple cell models of HD, making ApiCCT1 a promising therapeutic for HD. We find that recombinant ApiCCT1 ($ApiCCT1_r$), when exogenously delivered to cells, is able to enter both PC12 cells and primary cortical neurons (PCNs) and localize to the nucleus. Current studies focus on developing approaches to deliver $ApiCCT1_r$ to the brain, taking advantage of the ability of ApiCCT1 to penetrate cell membranes. We are investigating the use of both neural stem cells and viral vectors to deliver a secreted form of ApiCCT1 into the striatum of HD mice to provide continuous delivery of

ApiCCT1. Preliminary *in vivo* data suggests that direct injection of purified ApiCCT1$_r$ and mNSCs engineered to secrete ApiCCT1 (sApiCCT1) significantly reduce oligomeric mHTT following striatal transplantation in HD mice. Additional pilot studies indicate that R6/1 mice given intrastriatal injection of AAV2/1-sApiCCT1 show reduced oligomeric mHTT, fewer cells containing inclusion bodies, and behavioral improvements. Experiments are ongoing to test additional viral vectors. Preliminary data and published results suggest that *in vivo* delivery of secreted ApiCCT1 may provide an effective mechanism to modulate mHTT accumulation in HD.

Title: Effects of PARP-1 inhibition on CREB-binding protein in the striatal neuronal subpopulations of the R6/2 mouse model of Huntington's disease

Authors: *F. R. FUSCO[1], E. PALDINO[1], A. CARDINALE[1], I. SAUVE[1], V. D'ANGELO[2], C. GIAMPÀ[3];
[1]IRCCS Santa Lucia Fndn. Hosp., Rome, Italy; [2]Univ. of Rome Tor Vergata, Rome, Italy; [3]Catholic Univ. of Rome "Sacro Cuore", Rome, Italy

Abstract: Poly(ADP-ribose) polymerases (PARPs) are NAD-dependent enzymes able to catalyse the transfer of ADP-ribose units from NAD to substrate proteins. PARP-1 inhibitors have been studied because they reduce post-ischaemic and excitotoxic neuronal death. In fact, we have showed that INO-1001, a PARP 1 inhibitor, displays a neuroprotective effect in the R6/2 model of HD. In this study, we investigated the effects of PARP1-inhibition induced modulation of pCREB on CBP localization in the striatal neurons, and on the degeneration of parvalbuminergic interneurons, which are a particularly vulnerable subclass of striatal neurons. Transgenic mice were treated with INO 1001 20 mg/Kg daily starting from 4 weeks of age. Results: We found that INO-1001 treated R6/2 mice. Double-label immunofluorescence was performed to value the distribution of CBP in ubiquitinated NIIs in the striatum. INO-1001-treated and saline-treated brain sections were incubated with: goat anti-choline acetyl transferase (ChAT; Nova Biological); goat anti-nitric oxide synthase (NOS; Sigma, St-Louis, MO); mouse

anti-parvalbuminergic (PARV, chemicon) and mouse anti-calretinin (CALR; Chemicon).Morphometric evaluation and cell counts were performed. Our study showed that INO-1001 has a positive effect in sparing parvalbumin interneurons of the striatum, where CREB is upregulated by the compound. Moreover, CBP localization is positively influenced by INO-1001, where intraneuronal levels are reinstated in the R6/2 mouse. The sum of our data corroborates the previous observations indicating PARP inhibition as a possible therapeutic tool to fight Huntington's disease

Institute, Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Pridopidine is currently in clinical development for the treatment of Huntington disease (HD) and investigations to increase the understanding of its therapeutic benefit and mode of action are ongoing. Here we aim to investigate the efficacy and mechanism of action of pridopidine using the transgenic YAC128 mouse model of HD. Pridopidine was administered to animals starting at early (1.5 months of age) or late stages of disease (8 months of age). In the early treatment cohort, animals were divided into three groups receiving 0, 10, or 30 mg/kg of pridopidine for a period of 10.5 months. In the late cohort, animals were divided into two groups

receiving either 0 mg/kg or an escalating dose of pridopidine (10 mg/kg in week 1, 20 mg/kg in week 2, and 30 mg/kg in weeks 3-8). Pridopidine treated animals were evaluated using a battery of behavioural tests. Our analysis reveals that chronic treatment with pridopidine improves behavioural measures including motor learning, motor performance and depressive phenotypes in the YAC128 HD mice. Specifically, pridopidine improved motor learning in the rotarod test, and motor performance in the accelerating rotarod and climbing tests, immobility in the forced swim test of depression, and decreased anxiety-like behaviour in the open field test. Follow-up studies currently underway are examining the effect of acute pridopidine treatment on motor and depressive phenotypes. Ongoing analyses to address the impact of pridopidine treatment on neuropathological measures include structural MRI, immunohistochemical and stereological assessments of striatal regions. Finally, molecular studies examining putative targets of pridopidine activity will shed light on its mode of action in the YAC128 HD mice. Overall, our study supports continued clinical development of pridopidine for HD.

Abstract: Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder caused by an expansion of CAG repeats in the HD gene. Reduction of mutant huntingtin (muHtt) through protein interference or conditional gene knockout could prove to be an effective therapy. Previous work established allele-specific targeting and silencing by designing transcription activator-like effectors (TALE) to target single-nucleotide polymorphisms (SNP) in the mutant allele with a KRAB to promote transcriptional repression. We developed multiple TALEs that significantly reduce muHtt at the RNA and protein level without affecting the healthy allele in HD fibroblasts. Up to a 75% reduction of the mutant allele was observed following purification of only cells that received the TALE. The current study focuses on the examination of our lead TALE, T3γ, in a panel of adult and juvenile HD fibroblasts, primary YAC128 cortical and striatal neurons, and following injection in the YAC128 transgenic mouse model of HD. T3y was selected as our lead candidate TALE based on high global minor allele frequency score, robust gene silencing, allele-specificity, and the presence of its target SNP in the YAC128 HD mouse. Mutant allele knockdown was observed across multiple adult and juvenile HD fibroblasts following T3y treatment, demonstrating consistent gene silencing.
Preliminary data has shown robust expression of T3y-KRAB following in-vivo transfection using plasmid DNA complexed with a cationic polymer, TurboFect. However, limited biodistribution was observed. Our *in vitro* data indicates that wider coverage of target tissue with our TALE is vital for effective gene silencing. Presently, we compared the delivery of T3y-KRAB with: Invivofectamine (IVV), adeno-associated virus (AAV), and lipid nanoparticles (LNP) while using TF as our baseline control. IVV is a lipid-based RNA-delivery vesicle that has shown high *in vivo* transfection efficiency and gene silencing following *in vivo* injection in mice. AAV has been well tolerated in a number of clinical trials for neurodegenerative diseases and has demonstrated strong local cell penetrance. Finally, LNPs have shown to have strong potential as a delivery vehicle for biopharmaceuticals by complexing with ApoE secreted by astrocytes, allowing it to be uptaken by neurons and glia with minimal in-vivo toxicity and immunogenicity. We compared transgene expression, biodistribution, toxicity, and muHtt silencing following striatal injection of T3y-KRAB in the YAC128xNSG mouse model. Identification of both a potent and widespread delivery vehicle will be necessary to advance our target therapy to long-term functional efficacy studies.

Title: The effects of environmental enrichment on myelination and oligodendroglia in the YAC128 model of Huntington's disease

Authors: *C. I. RADULESCU, M. GARCIA-MIRALLES, C. FERRARI BARDILE, M. A. POULADI;
Translational Lab. in Genet. Med. (TLGM), A*STAR Singapore, Singapore, Singapore

Abstract: An enriched environment (EE) is comprised of conditions that facilitate sensory, motor, cognitive and social stimulation, along with access to novelty and complexity. In animal studies, enrichment has been shown to improve, or delay, motor and cognitive deficits in several neurological and neurodegenerative disorders. In contrast, social isolation has been revealed to contribute to cognitive decline, and have negative effects on development and aging. Furthermore, robust evidence supports an association between behavioural experience and neurogenesis, and increasingly a link between environmental conditions, oligodendrogenesis and myelination is becoming apparent. White matter abnormalities have recently been exposed in the early stages of Huntington disease (HD), an autosomal dominant neurodegenerative disorder characterised by motor, cognitive and psychiatric disturbances. In the current study we investigated the impact of environmental enrichment on HD-related phenotypes in the YAC128 mouse model, and in particular the extent to which the status of the environment could modulate myelination and oligodendroglia. Animals of mixed gender and genotype (wild type and YAC128) were allocated to one of three conditions: (a) EE, (b) standard housing, or (c) socially isolated and deprived housing. Enrichment involved larger than standard housing, increased social contact, complex nesting, appropriate sheltering, and the inclusion of objects of various size, shape and texture. Animals were kept in their assigned condition for 12 weeks prior to testing. Mice were evaluated using tests of motor, anxiety and depressive behaviour over the course of two weeks to examine the impact of enrichment or social isolation on behavioural HD phenotypes. On-going assessments include behavioural analysis, transcriptional analysis of myelin-related genes, ultrastructural characterization of myelin sheaths using electron microscopy imaging, and stereological analysis of oligodendroglia cellular populations. Our

results on the effects of EE and social isolation on myelination and oligodendroglia, in both the HD and the healthy brain, may have important therapeutic implications for diseases involving white matter pathology such as HD.

Title: Association between abnormal interhemispheric information transfer and corpus callosal structure in premanifest Huntington's disease

Authors: *H. E. CRAWFORD[1], A. MULICK CASSIDY[2], S. J. TABRIZI[1], R. I. SCAHILL[1]; [1]Huntington's Dis. Res. Centre, UCL, London, United Kingdom; [2]Dept. of Med. Statistics, London Sch. of Hyg. & Tropical Med., London, United Kingdom

Abstract: Recent research has found evidence of significant corpus callosal atrophy in Huntington's disease (HD), even many years prior to disease onset. The corpus callosum (CC) plays a significant role in interhemispheric information transfer (IIT) and is involved in many cognitive processes by way of its connectivity to numerous brain areas. The present study aimed to better understand how known degeneration of the CC in HD affects IIT, particularly in the premanifest stage, as well as investigate the association between IIT and CC volume and microstructural integrity.

An IIT task was administered to 12 premanifest HD and 14 healthy control subjects at two time points, one year apart. This very simple, unimanual reaction time (RT) task was designed to measure the transfer of information across the CC by exploiting the process of how stimuli presented to the left or right visual field is projected to the contralateral hemisphere. Linear regression models tested for within- and between-group differences in RT due to hand dominance and the crossing of stimulus presentation and hand response, as well as the between-group difference in IIT RTs. Regression models also examined the association between IIT and CC volume, as well as between IIT and the microstructural integrity of CC tracts, measured using 3T MRI and DTI, data which was collected previously as part of the TrackOn-HD study. Preliminary analysis of the cross-sectional behavioural results revealed that despite premanifest

HD subjects demonstrating overall slower RTs, there was no evidence of a difference in IIT RT between the groups. The groups however did demonstrate a reversal of IIT RTs. A larger crossed-uncrossed difference (CUD) for the non-dominant hand in healthy controls suggests that IIT takes longer to transfer from the dominant to the non-dominant hemisphere, whereas a larger dominant hand CUD in premanifest HD subjects suggests that IIT actually takes longer in the opposite direction.
A negative association between CC volume and fractional anisotropy (FA) in the genu tracts of the CC and non-dominant hand IIT was found in premanifest HD subjects. This suggests that as CC volume and FA decreases, the time it takes for information to cross between hemispheres, specifically from the dominant to the non-dominant hemisphere, increases.
In conclusion there is clearly an abnormality in premanifest HD subjects' IIT compared with controls, specifically when using the non-dominant hand but whether this is due to premanifest HD subjects being slower to respond overall is yet to be determined. Further analysis is needed to ascertain the exact patterns of IIT and to better elucidate the link between CC structure and function.

Title: Dynamic functional network connectivity differences between prodromal Huntington's disease & healthy control subjects

Authors: F. A. ESPINOZA[1], R. MILLER[1], E. MENNIGEN[1], V. M. VERGARA[1], J. A. TURNER[2], M. MISIURA[2], J. CIAROCHI[2], H. JOHNSON[3], J. D. LONG[3], J. BOCKHOLT[3], J. S. PAULSEN[3], *V. CALHOUN[1];
[1]The Mind Res. Network, Albuquerque, NM; [2]Dept. of Psychology and Neurosci., Georgia State Univ., Atlanta, GA; [3]Dept. of Psychiatry, Univ. of Iowa, Iowa City, IA

Abstract: Background: Huntington's disease (HD) is a neurodegenerative disorder caused by a cytosine-adenine-guanine (CAG) expansion ≥36 in the HTT gene. HD affects motor coordination, leads to mental decline, and presents behavioral symptoms. Subtle changes in

motor and cognitive skill can be detected decades prior to receiving a diagnosis of HD. This time epoch is typically referred to as the prodrome of HD. Previous structural brain studies have shown that HD progress is characterized by striatal atrophy and cortical changes. In this study, we used resting-state functional magnetic resonance imaging (rsfMRI) to explore time-varying connectivity differences between individuals in the HD prodrome (prHD) and healthy control (HC) subjects by group independent component analysis (ICA).
Methods: We selected a sample of 261 subjects (183 prHD and 78 HC) from the PREDICT-HD study. Group ICA was used to decompose the rsfMRI data into 100 maximally spatially independent components (ICs) and associated time-courses (TCs), of which 46 ICs were identified as meaningful resting-state networks (RSNs) and were categorized into 8 functional domains. Using the sliding windows method, 106 dynamic functional network connectivity (FNC) matrices were estimated per subject as the pairwise correlations among the 46 RSN TCs. A k-means algorithm was used to assign FNC matrices into 4 clusters representing discrete states. Finally, multiple regression analysis with age, gender, CAG, and motion regressors was applied to each FNC state.
Results: The CAG variable and univariate test were used to identify group differences (significance was assessed at $p<0.05$ and FDR corrected). Only states 3 and 4 showed significant group differences. State 4 resembles the static FNC matrix including a negative correlation between CAG and the connectivity in the visual network. In addition, negative correlations between CAG and the interactions among subcortical network and default mode and salience networks; auditory and default mode, are observed only in the dynamic analysis. In state 3, we see multiple negative effects of CAG on connectivity to the putamen and thalamus involving auditory, cerebellar, cognitive control, default mode, salience, sensorimotor. Controls also spend significantly more time in state 3 compared to pro-HD.
Conclusions: Findings show significant dynamic functional connectivity differences between prHD and HC subjects in specific networks consistent with previous static analyses. In sum, prHD exhibit substantial dynamic connectivity differences relative to controls in rsfMRI data suggesting transient disruptions of connectivity may be a hallmark of the disease.

Title: Phosphorylation of respiratory chain components by mitochondrial c-Src is required for neuronal viability

Authors: *M. OGURA, J. YAMAKI, M. K. HOMMA, Y. HOMMA;
Dept. of Biomolecular Sci., Fukushima Med. Univ. Sch. of Med., Fukushima, Japan

Abstract: Reversible protein phosphorylation is emerging as an important mechanism to modulate mitochondrial functions. Expression level of non-receptor-type tyrosine kinase c-Src is relatively high in mitochondria. The Src family kinase inhibitor amino-5-(4-chlorophenyl)-7-(*t*-butyl) pyrazolo [3,4*d*] pyrimidine (PP2) exhibits significant reduction of respiration and production of reactive oxygen species (ROS). Similar results were obtained from cells expressing kinase-dead c-Src, which harbors a mitochondrial-targeting sequence. These results suggest that c-Src is involved in mitochondrial energy production and cell survival. In this study, we have identified novel substrates of c-Src in mitochondria and investigated their function in the regulation of oxidative phosphorylation and cell viability. Phosphorylation-site analysis selects c-Src targets, including NADH dehydrogenase [ubiquinone] flavoprotein 2 (NDUFV2) at Tyr193 of respiratory complex I and succinate dehydrogenase A (SDHA) at Tyr215 of complex II. Comparison of cells expressing wild-type and their phosphorylation-defective mutants reveals that NDUFV2 phosphorylation is required for NADH dehydrogenase activity and ATP production. SDHA phosphorylation is not required for enzyme activity, but required for efficient electron transfer. Expression of its phosphorylation-defective mutant induces significant amounts of ROS. Loss of viability is observed in the primary neurons expressing these mutants. The cleavage of poly (ADP-ribose) polymerase-1 is also observed in cells expressing NDUFV2 mutant, but not SDHA mutant, suggesting that NDUFV2 phosphorylation is required for prevention of apoptosis. These results suggest that mitochondrial c-Src regulates the oxidative phosphorylation by phosphorylating respiratory components and cell survival.

Title: Docosahexaenoic acid (DHA) protects Schwann cells against palmitic acid-induced lipotoxicity through P38 but not JNK MAPK

Authors: *M. DESCORBETH[1], M. DE LEON[2];
[1]Ctr. for Hlth. Disparities and Mol. Medecine, Loma Limda Univ., Loma Linda, CA; [2]Loma Linda Univ., Loma Linda, CA

Abstract: Saturated fatty acids induce cell and tissue damage in the nervous system, whereas docosahexaenoic acid (DHA), an n-3 polyunsaturated fatty acid, shows a neuroprotective effect. The mechanism by which DHA protects the nervous system is unclear. In this study, we examined the contribution of the P38 and JNK MAPK pathways in the protective effect of DHA under palmitic acid-induced lipotoxicity (PA-LTx). We cultured primary Schwann cells in euglycemic (EG) (5.5 mM glucose) and hyperglycemic (HG) (17 mM glucose) conditions for 5 days and then treated them with PA: BSA (300 μM: 150 μM) in the presence or absence of DHA (50 μM) for up to 48 hrs. We used selected MAPK inhibitors to investigate the implication of P38 and JNK pathways in the DHA protection of pSC from PA-LTx. We showed that PA induced SC death, and that was associated with an increase in the phosphorylation of P38 and JNK in EG and HG groups. The addition of SB, a P38 inhibitor, or JNK II, a JNK inhibitor, with PA did not prevent PA to induce cells death. However, the combination of both inhibitors in presence of PA restored the cell viability in both groups. When we co-treated Schwann cell with DHA and PA the cell viability was also restored. In addition the chromatin condensation, an apoptosis feature, induced by PA was eliminated in the presence of DHA. Furthermore, DHA also restored P38 but not JNK phosphorylation to the control levels. In conclusion, we show that PA induced cell death through the P38 and JNK pathways and that DHA protects Schwann cells against PA by regulating P38 but not the JNK pathway.

Title: Cysteine s-nitrosylation of neuroprotective protein prohibitin modulates mitochondrial dynamics in neurons

Authors: L. QIAN, Y. QU, G. MANFREDI, C. IADECOLA, *P. ZHOU;
Brain and Mind Res. Inst., Weill Med. Coll Cornell Univ., New York, NY

Abstract: The neuroprotective mitochondrial protein Prohibitin (PHB), is upregulated in a nitric oxide (NO) dependent manner upon ischemic preconditioning induction. However, the mechanisms of NO modulation of PHB remain to be elucidated. We had previously determined that PHB is nitrosylated at its only cysteine residue (Cys^{69}). Here, we focused on the effects of PHB nitrosylation on mitochondrial fission and fusion, the fundamental processes by which the imbalance result in cell degeneration (Chen and Chan 2010). We hypothesized that mitochondrial dynamics could be altered, if Cys^{69} were mutated to eliminate PHB nitrosylation. We tested this hypothesis by first transfecting neurons with PHB siRNA to downregulate endogenous PHB and then co-transfecting them with mt-dsRed to visualize mitochondria and C69V-PHB, a mutant DNA construct, in which the Cys^{69} is changed to Val. Five days later, live cell imaging of mt-dsRed was captured. Neurons were divided into three categories based on their mitochondrial morphology in neurites: neurons with normal elongated, with fragmented, or a mixture of normal and fragmented, mitochondria. The majority of neurons transfected with mt-dsRed only (control) had elongated mitochondria (65.6±3 % vs. 17.6±3% fragmented). Transfection with siRNA alone resulted in endogenous PHB decrease (50%) associated with an increase of neurons with fragmented mitochondria (30.7±3 % elongated vs 44.1±2 fragmented). Transfection of PHB silenced neurons with WT-PHB largely restored mitochondrial morphology to control levels (68.8±4% elongated vs 14.5±3 fragmented), while C69V-PHB failed to do so (31±1 elongated vs 42.2 fragmented, $p<0.05$, n=3 with 250 cells/each group). We next modulated NO levels by pretreating cells with either an NO donor (DPTA, 25 μM) or a NOS inhibitor (L-NAME, 100μM) to assess the relationship between NO and mitochondrial morphology. Neurons transfected with mt-dsRed (control) showed NO dependent mitochondrial morphological changes (vehicle 62.6±4, DPTA: 81.2±3, L-NAME: 46.3±2 elongated mitochondria). Neurons transfected with siRNA and WT-PHB showed similar mitochondrial morphology to controls (vehicle: 65.5±2, DPTA: 78.3±3, L-NAME: 54.5± 2), while neurons transfected with siRNA and CV-PHB did not respond to NO modulation (vehicle: 39.9±2, DPTA: 41.7±4, L-NAME: 39.7±1). These data indicated that a mutant CV-PHB fails to influence mitochondrial dynamics, suggesting that Cys^{69} is critical for the normal function of PHB in regulating mitochondrial fusion and fission in response to NO. Ongoing studies are addressing the mechanisms whereby Cys^{69} nitrosylation regulates PHB levels and function in neurons.

Title: Orexin A attenuates palmitic acid-induced hypothalamic cell death

Authors: *C. M. DUFFY[1,2], J. P. NIXON[2,1], T. A. BUTTERICK[2,1,3];
[1]Food Sci. and Nutr., Univ. of Minnesota, Saint Paul, MN; [2]Minneapolis Veterans Affairs Hlth. Care Syst., Minneapolis, MN; [3]Minnesota Obesity Ctr., Saint Paul, MN

Abstract: Palmitic acid (PA), an abundant dietary saturated fatty acid, contributes to obesity and hypothalamic dysregulation in part through increase in oxidative stress, insulin resistance, and neuroinflammation. Increased production of reactive oxygen species (ROS) as a result of PA exposure contributes to the onset of neuronal apoptosis. Additionally, high fat diets lead to changes in hypothalamic gene expression profiles including suppression of the anti-apoptotic protein B cell lymphoma 2 (Bcl-2) and upregulation of the pro-apoptotic protein B cell lymphoma 2 associated X protein (Bax). Orexin A (OXA), a hypothalamic peptide important in obesity resistance, also contributes to neuroprotection. Prior studies have demonstrated that OXA attenuates oxidative stress induced cell death. We hypothesized that OXA would be neuroprotective against PA induced cell death. To test this, we treated an immortalized hypothalamic cell line (designated mHypoA-1/2) with OXA and PA. We demonstrate that OXA attenuates PA-induced hypothalamic cell death via reduced caspase-3/7 apoptosis, stabilization of Bcl-2 gene expression, and reduced Bax/Bcl-2 gene expression ratio. We also found that OXA inhibits ROS production after PA exposure. Finally, we show that OXA treatment alters mHypoA-1/2 intracellular metabolism, resulting in increased basal respiration, maximum respiration, ATP production, and reserve capacity. Collectively, these results support that OXA protects against PA-induced hypothalamic dysregulation, and may represent one mechanism through which OXA can ameliorate effects of obesogenic diet on brain health.

Title: A mitochondrial division inhibitor, Mdivi-1, inhibits mitochondrial fragmentation and attenuates kainic acid-induced hippocampal cell death

Authors: *H. KIM[1], J. LEE[1], K. PARK[2], W.-H. KIM[2], G. ROH[1];
[1]Gyeongsang Natl. Univ. Sch. of Med., Jinju, Korea, Republic of; [2]Korea Natl. Inst. of Hlth., Osong, Korea, Republic of

Abstract: Kainic acid (KA)-induced excitotoxicity promotes cytoplasmic calcium accumulation, oxidative stress, and apoptotic signaling, leading to hippocampal neuronal death. Mitochondria play a critical role in neuroinflammation and the oxidative stress response. Mitochondrial morphology is disrupted during KA-induced seizures; however, it is not clear whether mitochondrial fission or fusion factors are involved in KA-induced neuronal death. We investigated the effect of Mdivi-1, a chemical inhibitor of the mitochondrial fission protein Drp1, on mitochondrial morphology and function in KA-injected mice. Mdivi-1 pretreatment significantly reduced seizure activity and increased survival rates of KA-treated mice. Mdivi-1 was protective against mitochondrial morphological disruption, and it reduced levels of phosphorylated Drp1 (Ser616) and Parkin recruitment to mitochondria. By contrast, levels of mitochondrial fusion factors did not change. Mdivi-1 also reduced KA-induced neuroinflammation and glial activation. We conclude that inhibition of mitochondrial fission attenuates Parkin-mediated mitochondrial degradation and protects from KA-induced hippocampal neuronal cell death.

Title: Excessive D-serine mediates cell death in developing neuron

Authors: *M. SUZUKI, J. SASABE, S. AISO;
Keio Univ. Sch. of Med., Tokyo, Japan

Abstract: Neuronal cell death is observed in neurodegenerative disorders such as Alzheimer's disease, Parkinson's disease, and amyotrophic lateral sclerosis. One possible mechanism of cell death is hyper-stimulation of glutamate receptors, which activates apoptotic pathway in neuron. D-serine is a co-agonist of *N*-Methyl-D-Aspartate type glutamate receptor (NMDAR), and modulates NMDAR activity. Although excessive D-serine is reported to cause hyper-activation of NMDAR and cell death, the mechanism is yet to be identified.
In this study, we found novel apoptotic stimulation on developing neurons. Treatment of D-serine in the absence of L-serine causes caspase-3 dependent apoptosis. D-serine mediated activation of caspase-3 in primary neurons at immature stage (DIV4) but not mature stage (DIV16). In addition, the cell death was occurred in cortical neurons but not in cerebellar neurons.
Although NMDAR excitotoxicity results in activation of neuronal nitric oxide synthase (nNOS), NOS inhibitor did not suppressed apoptosis. Inhibitor for NMDAR (MK-801 and 5,7-dichlorokynurenic acid), for AMPAR (DNQX), or Ca2+ chelator (EGTA) did not inhibit D-serine dependent cell death. However, only L-serine can completely suppressed D-serine dependent apoptosis.
Because L-serine is known as neurotrophic amino acids supplied from glial cells in central nervous system, D-serine might interfere with the neurotrophic effect of L-serine on neurons.

Title: The adaptor protein p66shc regulates metabolism, ros production, and amyloid beta sensitivity in cns cells

Authors: *A. LONE[1], R. C. CUMMING[2];
[1]Biol., [2]Dept. of Biol., Western Univ., London, ON, Canada

Abstract: A key pathological feature of Alzheimer's disease (AD) is the accumulation of extracellular deposits of amyloid beta (Aß) peptide within the brains of affected individuals. Aß accumulation is associated with oxidative stress, extensive neuronal death and synaptic loss. However, 40% of the elderly have pronounced Aß deposition within their brains, yet show no symptoms of dementia, indicating that some cells are resistant to Aß toxicity. Several studies suggest that central nervous system (CNS) cells that are resistant to the harmful effects of Aß display a metabolic shift from mitochondrial-dependent oxidative phosphorylation (OXPHOS) to aerobic glycolysis for their energy needs. The adaptor protein p66SHC has been shown to play a definitive role in aging, as well as in regulation of redox balance and ROS levels. Recent studies have shown that p66SHC expression and activation can shift the cellular metabolic state from OXPHOS to aerobic glycolysis. Hence, we propose that the expression and activation of p66SHC in CNS cells promotes both increased OXPHOS and sensitivity to Aß toxicity. To test this hypothesis, we transiently overexpressed p66SHC in a rodent neuronal cell line, and knocked down endogenous p66SHC in a rodent glial cell line, to determine the effect of p66Shc activation on metabolic activity. Changes in mitochondrial ROS levels and mitochondrial electron transport chain (ETC) activity were also measured. We examined the subcellular localization of the phosphorylated and activated form of p66SHC. Lastly, we investigated if p66SHC expression and activation affected sensitivity to Aß in both neuronal and glial cell lines in an OXPHOS dependent manner. Transient overexpression of p66SHC repressed glycolytic enzyme expression and increased mitochondrial ETC activity and ROS levels. The opposite effect was observed when endogenous p66SHC expression was knocked down. Exposure to Aß promoted the phosphorylation and activation of p66SHC, resulting in an upregulation of mitochondrial metabolism. Moreover, expression and activation of p66SHC increased sensitivity to Aß toxicity. Our findings indicate that expression and activation of p66SHC renders CNS cells more sensitive to Aß toxicity by promoting mitochondrial OXPHOS while repressing aerobic glycolysis. Thus, p66Shc may represent a therapeutically relevant target for the treatment of AD.

Title: Genetic manipulation of mTORC1 signaling in mouse cerebellar Purkinje cell

Authors: ***H. KASSAI**[1], Y. SAKAI[1], H. NAKAYAMA[4], T. MAEDA[2], K. HASHIMOTO[4], M. KANO[3], A. AIBA[1];
[1]Grad. Sch. of Med., [2]Inst. of Mol. & Cel. Biosci, [3]Univ. of Tokyo, Tokyo, Japan; [4]Hiroshima Univ., Hiroshima, Japan

Abstract: Mammalian target of rapamycin (mTOR) is an evolutionarily conserved serine/threonine kinase, and functions as two distinct complexes, termed mTORC1 and mTORC2. The mTORC1 pathway is activated by amino acids or growth factor stimuli, and plays a central role in cell growth processes such as protein synthesis and autophagy. Abnormal mTOR signaling is often found in many neurological diseases such as tuberous sclerosis, autism and neurodegenerative diseases. Since all these diseases are associated with chronic activation of mTORC1 pathway, we focused on addressing mTOR functions in these diseases by establishing animal models of chronically activated mTORC1 pathway in cerebellar Purkinje cells. We used constitutively active mutant of mTOR, which retains its kinase activity even under starvation conditions. We crossed two lines of transgenic (Tg) mice; TRE-mTOR Tg in which active mTOR is linked to TRE promoter, and L7-tTA Tg in which tTA expression is driven by Purkinje-cell specific L7 promoter. In double Tg mice (L7-mTOR Tg mice, hereafter), expression of active mTOR in Purkinje cells did not affect the gross appearance or fertility. However, we found many abnormalities in the morphology of Purkinje cells in L7-mTOR Tg mice, such as enlarged soma, thickened dendrites and increased number of self-crossings. In addition, the number of Purkinje cells began to decrease by apoptotic cell death from 3 weeks of age in the Tg mice. These results indicate that mTORC1 signaling is important for morphology and survival of cerebellar Purkinje cells.

Title: Bcl-XL knockout attenuates mitochondrial respiration and shifts cellular metabolism towards the pentose phosphate pathway

Authors: *A. METHNER[1], A. PFEIFFER[2], J. SCHNEIDER[2], A. DOLGA[3], T.-D. VOSS[4], J. LEWERENZ[4];
[1]Johannes Gutenberg Univ. Mainz, Mainz, Germany; [2]Johannes Gutenberg Univ., Mainz, Germany; [3]Univ. of Groningen, Groningen, Netherlands; [4]Univ. of Ulm, Ulm, Germany

Abstract: Bcl-XL is an anti-apoptotic protein mainly localized to the outer mitochondrial membrane which enhances mitochondrial bioenergetics by controlling Ca^{2+} influx into the mitochondria. Here, we performed an in-depth analysis of the effect of mitochondrial Bcl-xL on mitochondrial shape and function in well-characterized knockout (KO) and rescue fibroblast cell lines. KO mitochondria were more fragmented and exhibited reduced oxidative phosphorylation and electron transfer capacity with convergent complex I and II electron input suggesting a predominance of other means of ATP generation like glycolysis or the pentose phosphate pathway (PPP). Inhibition of ATP synthase with oligomycin treatment indeed resulted in an instant increase in acidification of the growth medium in line with an instant switch to glycolysis. In the presence of galactose, KO cells were also more susceptible to mitochondrial toxins. Under steady-state conditions, however, KO cells did not have an increased glycolytic activity. Apparently, these cells can turn on glycolysis more efficiently than wildtype cells on demand. The pentose phosphate shunt is another major pathway used by cells to generate NADPH that can be used to reduce oxidized glutathione (GSH), a major cellular antioxidant. It also has a prominent anabolic function by generating phosphopentoses and ribonucleotides. KO cells had an increased abundance and function of the rate-limiting enzyme glucose-6-phosphate dehydrogenase, more NADPH, more GSH and an increased growth rate but were not protected against oxidative stress. We therefore concluded that reduced mitochondrial respiration caused by malfunctioning mitochondria lacking Bcl-XL is compensated by increased use of glucose in the pentose phosphate shunt.

Title: Investigating the protective effects of mitochondrially targeted telomerase on neuronal metabolism and resistance to amyloid-beta

Authors: *O. S. SINGH, R. C. CUMMING;
Dept. of Biol., Western Univ., London, ON, Canada

Abstract: Telomerase consists of two main components that function as dimers; the telomerase RNA component (TERC) and the telomerase reverse transcriptase (TERT). TERT catalytically adds TTAGGG hexanucleotide repeats to the 3' end of the lagging strand of chromosomes thereby preventing telomere shortening during DNA replication in mitotic cells. While telomerase is highly expressed in germ line cells, embryonic stem cells, and malignant cancer cells, there is increasing evidence of a non-telomeric function of TERT in post-mitotic cells. Recent studies have revealed that extra-nuclear TERT may protect neurons from apoptosis, ischemic cell death, N-methyl-D-aspartate receptor (NMDA)-induced neurotoxicity, and glutamate cytotoxicity. More importantly, when cells experience oxidative stress, TERT can translocate from the nucleus to the mitochondria and promote a decrease in mitochondrial reactive oxygen species (ROS) production while increasing mitochondrial membrane potential. Mitochondrial localized TERT has been detected in both primary neuronal cultures and in hippocampal neurons of Alzheimer's disease (AD) brains. Mitochondrial dysfunction is a prominent feature of many neurodegenerative diseases including AD. A major pathological feature of AD is the progressive accumulation of amyloid-beta (Aβ) peptide within the cortex and hippocampus. It has been shown that Aβ oligomers directly interfere with mitochondrial respiration by binding to alcohol dehydrogenase (ABAD) thereby promoting mitochondrial dysfunction, ROS production, and cell death. Hence, we hypothesized that TERT may protect neurons from mitochondrial dysfunction and Aβ toxicity via metabolic reprogramming. We have created stable cell cultures with doxycycline inducible expression of TERT in the murine hippocampal neuronal cell line HT-22. Induction of TERT expression in HT22 cells resulted in altered glycolytic enzyme activity, mitochondrial membrane potential and ROS production. We are currently determining if TERT localizes to mitochondria and confers neuroprotection against Aβ toxicity via metabolic reprogramming. The results from this study may lead to a novel potential therapy for the treatment of AD.

Title: Role of motochondrial oxidative stress and UCP2 in epilepsy experimental model induced by pilocarpine

Authors: *M. B. NEJM[1], M. MARQUES, 04034032[2], A. HAIDAR[2], F. SCORZA[2], E. CAVALHEIRO[2];
[1]Federal Univ. of Sao Paulo, Sao Paulo, Brazil; [2]Federal Univ. of Sao Paulo, São Paulo, Brazil

Abstract: Temporal lobe epilepsy (TLE) is the most common form of epilepsy in humans. Evidence supports the fact that neuronal injury observed in epilepsy may be the result of an overproduction of free radicals (oxidative stress) and related to excitotoxicity event. Mitochondria is responsible for ATP synthesis but also is involved in calcium uptake and release, transient mitochondrial permeability and in ROS (Reactive Oxygen Species) generation. It is known that excessive ROS generation can promote ultrastructural changes in the respiratory chain. The first uncoupling protein mitochondrial of respiratory chain (UCP - Uncoupling Mitochondrial Protein) described was UCP1 and others subsequently were discovered. UCP2 is significantly expressed in certain brain regions and is responsible for stabilizing the mitochondrial membrane potential, an important event suggested to reduce cell death. It was suggested that activation of UCP2 may protect neurons in degenerative processes associated with oxidative stress and mitochondrial changes in potential trasmembrana so, may be therefore, neuroprotective or the brain. Antioxidant agents, at low concentrations compared with the oxidizable substrate, can reduce or prevent oxidation, also helping to combat oxidative stress. This raises the proposal to clarify from the beginning of epileptogenesis and over the periods of pilocarpine experimental model of epilepsy, UCP2 participation using small interfering RNA for this protein. We aim to evaluate: phenotypic changes on pilocarpine experimental model (mortality, latency to develop Status epilepticus (SE) and frequency of seizures); expression of UCP2 and antioxidant enzymes (MnSOD and GPx) in hippocampus mitochondria; enzymatic activity of respiratory chain complexes; presence of neuronal death; production of ROS; and morphology of these mitochondria. So far, the obtained results show efficacy in UCP2 silencing verified by the reduction of protein expression. We can therefore speculate about UCP2

neuroprotective role since these animals showed high mortality and reduced latency to develop the SE; also it were showed increased neuronal death and ROS production, including from mitochondrial origin. The silencing, even occasionally, promoted important changes. With the results that we will still get we intend to elucidate the neuroprotective role of UCP2 as long-term silencing effects in animals from the chronic group.

Title: Epigenetic regulation of endophilin-B1 promotes neuronal viability in response to disease and injury

Authors: ***R. S. MORRISON**[1], D. B. WANG[1], Y. KINOSHITA[1], C. KINOSHITA[1], R. LEE[1], S. P. MURPHY[1], B. L. SOPHER[2], G. A. GARDEN[2];
[1]Dept Neurolog. Surgery, [2]Dept of Neurol., Univ. Washington, Seattle, WA

Abstract: Epigenetic changes in gene expression are implicated in neuronal dysfunction associated with neurodegenerative and acute brain disorders as well as normal aging. Histone deacetylase-2 (HDAC2) is a member of an enzyme family that catalyzes the removal of acetyl groups on lysine residues of histone proteins, leading to altered chromatin structure and gene expression. HDAC2 is upregulated during neuronal differentiation, comprising the major HDAC protein in adult brain. In Alzheimer's disease (AD), HDAC2 is elevated, repressing expression of several genes necessary for synaptic function, learning and memory. However, the impact of elevated HDAC2 on neuronal gene expression in AD, aging brain or neuronal injury remains poorly understood. Here we demonstrate that HDAC2 overexpression in cultured primary cortical neurons represses expression of endophilin B1, also known as Bax-interacting factor-1

(Bif-1). We recently showed that Bif-1 is a neuroprotective protein that stimulates mitochondrial elongation. Importantly, we demonstrated that neuron-specific isoforms of Bif-1 are reduced in human AD cortex and CNS tissue from mouse models of AD and ischemic stroke. HDAC2 overexpression also enhanced caspase 3 activation and repressed expression of mitofusin 2, a protein that promotes mitochondrial fusion. We further demonstrate that HDAC2 knockdown in mouse primary cortical neuron cultures protects against beta-amyloid induced mitochondrial damage, caspase activation and apoptosis while restoring Bif-1 protein levels. The protective effect of HDAC2 knockdown was abrogated by Bif-1 shRNA and in Bif-1 deficient neurons. HDAC2 genetic deficiency also enhanced neuronal survival and minimized the loss of Bif-1 in the middle cerebral artery occlusion model of cerebral ischemia. HDAC2-dependent regulation of Bif-1 was neuron-specific and not observed in mouse embryo fibroblasts. These findings support the hypothesis that HDAC2 represses Bif-1, a critical neuroprotective protein, and other regulators of mitochondrial dynamics, sensitizing neurons to stress-induced mitochondrial dysfunction and apoptotic cell death.

Title: Altered molecular processes of malignant peripheral nerve sheath tumors support the PTP closure state driving anti-apoptotic tumor progression

Authors: *D. DANIELS[1], B. C. PRUDNER[2], B. VAN TINE[2];
[1]Washington Univ. In St. Louis, Saint Louis, MO; [2]Washington Univ. in St. Louis, St. Louis, MO

Abstract: Sarcomas are malignant tumors of mesenchymal origin that arise from lymphatic, circulatory and connective tissue. Of the 13,000 soft tissue and bones cases diagnosed in the US, approximately 1% develop malignant tumors annually (McFarland 2015). Malignant Peripheral Nerve Sheath Tumors (MPNSTs) are atypical soft tissue sarcomas of neural origin that engender high morbidity in the afflicted when resection is not achievable. 50% of MPNSTs are NF1 associated and the other half arise spontaneously, creating a lifetime risk that 10% of NF1 patients will develop MPNSTs (Ratner 2015). Current therapeutics such as chemotherapy and radiation have minimal impact in MPNSTs and readily kill normal cells, therefore, cutting edge

sarcoma research has migrated to highly specific, antagonistic molecular modeled therapeutics.In cells, the mitochondria is known to function as the key energy generating and autophagic organelle and in cancer cells these entities have an even more prominent role in cellular function, metabolism and cell death (Verschoor 2012). Under stressful conditions normal cells undergo autophagic processes such as apoptosis to prevent the advancement of mutant cell survival and viability via mitochondrial membrane manipulation. Cancer cells have the unique capability to evade these auto-regulatory mechanisms thus promoting tumorigenesis. In normal cells the apoptotic mechanism, mitochondrial permeability transition pore (PTP) opening is directed by a series of molecular signals: mitochondrial depolarization, respiratory inhibition and generation of reactive oxygen species (ROS), release of Ca2+, swelling of the mitochondria leading to breaches in the outer membrane that engender the release of intermembrane protein, that brings about cell death (Rasola 2014). The induction of systems that stimulate PTP opening characteristics serve as promising models for the promotion of cell death in malignant tumors that have adopted anti-apoptotic traits such as MPNSTs.

Abstract: A better understanding of the mechanisms by which early pathological events (e.g., amyloid deposit) cause neurodegeneration in Alzheimer disease (AD) can help unravel the

pathogenesis of this complex heterogeneous disorder, and consequentially develop new therapeutic strategies. Integrating systems biology and experimental neurology approaches, we discovered the potential of an ovary-orientated protein OCIAD1 (Ovarian-Carcinoma-Immunoreactive-Antigen-Domain-Containing-1) as an etiopathological contributor in AD. The association between OCIAD1 and neurodegeneration in AD is revealed by analyzing the brain vulnerability-relevant gene signatures in sporadic AD patients and the functional partner network *in silico.* This is consistent to our previous finding in synaptic proteomics during disease progression in AD transgenic mice. In humans, OCIAD1 is co-expressed with several AD-associated genes in the brain, at particularly higher levels in the vulnerable brain areas correlated with disease severity. Under conditions mimicking early AD pathological changes, OCIAD1 is elevated in the neurons and partly associated with Aβ/GSK-3β/CTNNB1 signaling pathway. Moreover, an interaction between OCIAD1 and BCL-2 impairs the membrane potential of mitochondria, facilitating release of mitochondrial apoptotic factors and caspase 3 activation. Notably, knocking down OCIAD1 mitigates the aggravating effect of Aβ on apoptosis after exposure of multiple stressors. Our findings indicate that OCIAD1 is a common etiological factor linking brain vulnerability in AD to mitochondria dysfunction.

Title: The highly electronegative low-density lipoprotein l5 impairs the neuritogenesis in ngf-induced pc12 cells

Authors: ***C.-T. LEE**[1], C.-L. LAI[2], J.-Y. WANG[2];
[1]Hsin Sheng Junior Col. of Med. Care and Mana, Taoyuan City, Taiwan; [2]Grad. Inst. of Medicine, Col. of Medicine,Kaohsiung Med. Univ., Kaohsiung, Taiwan

Abstract: The patients with cardiovascular diseases (CVD) are often associated with the occurrence of cognitive decline and dementia. Low-density lipoprotein (LDL), which is one of the risk factor for CVD, may play a critical role; further, L5, a electronegative LDL with

relatively highest electronegative charge, is the most important candidate. So far, the biological effect of electronegative LDL on neuronal cell reactivity is fully unclear and has not been studied. Here, an in vitro cultured model of PC12 cell, a rat pheochromocytoma-derived cell line with neuronal characteristics, was used in this study. We treated the cells with L5, L1 (an LDL with lesser extent of electronegativity than L5) and oxidized LDL (an artificially synthesized LDL), and assayed for cytotoxicity and neuritogenesis. The results indicated that both oxLDL and L5 are toxic to PC12 cells in a dose-dependent manner. L1 exerted no effect on cell viability, hence exhibiting a non-neurotoxic characteristic. The toxicity of L5 at 50 μg/ml was not appeared until the cultures were treated for more than the duration of 24 h. Moreover, both L5 and oxLDL at 30 μg/ml, but not L1, leaded to the failure of NGF-induced neuritogenesis in PC12 cells, detected by neurite outgrowth assay. Further, we identified that L5 does not affect NGF receptor activity, but downregulates PI3K/Akt signaling, consequently impairing NGF-induced neuritogenesis. These results suggested that L5 itself has the cytotoxicity and impairs the neuritogenesis in NGF-induced neuron-like PC12 cells.

Title: PARP-1-dependent expression of pro-apoptotic factor bnip3 is mediated by hypoxia inducible factor-1α in hypoxic neurons

Authors: P. LU, S. ATOUI, *C. M. ANDERSON;
Univ. of Manitoba, Winnipeg, MB, Canada

Abstract: Oxidative genotoxicity in brain ischemia/hypoxia causes excessive activity of the nuclear enzyme poly(ADP-ribose) polymerase-1. The catalytic activity of PARP-1, in turn, leads to depletion of NAD^+, accumulation of ADP-ribose polymers, mitochondrial permeability and nuclear translocation of apoptosis-inducing factor (AIF). We recently demonstrated that the pro-death Bcl-2 protein family member Bcl-2/adenovirus E1B 19 kDa-interacting protein (Bnip3) acts as a mitochondrial mediator of PARP-1-induced mitotoxicity and neuron death. Here we

hypothesized that PARP-1-induced NAD^+ depletion inhibits sirtuin deacetylase activity, leading to enhanced acetylation-mediated HIF-1α stability and HIF-1-mediated transcription of Bnip3. Activation of PARP-1 by exposure of primary cortical neurons to hypoxia or normoxic genotoxic concentrations of the DNA alkylating agent, 1-methyl-3-nitro-1-nitroguanidine (MNNG), caused time-dependent depletion of cytoplasmic/nuclear NAD^+ levels, inhibition of sirtuin deacetylase activity and hyper-acetylation of HIF-1α. Chromatin immunoprecipitation using an anti-HIF-1α antibody, followed by qPCR, also revealed significant enhancement of HIF-1α binding to a HIF-responsive element in the Bnip3 upstream promoter region. All of these events, along with increased Bnip3 transcript levels, were mitigated in the presence of the PARP-1 inhibitor, PJ34 (10 μM), or in *parp-1*$^{-/-}$ neurons. This confirms PARP-1 dependence of hypoxic Bnip3 regulation and verifies a direct linkage between PARP-1 and Bnip3 regulation by HIF-1 following MNNG treatment. Moreover, silencing of HIF-1α using lentiviral shRNA delivery significantly reduced hypoxic HIF-1/Bnip3 HRE interaction and Bnip3 transcript levels, thereby demonstrating a direct role of HIF-1α in hypoxic Bnip3 expression. Together, these data suggest a regulatory role for HIF-1 in neurotoxic Bnip3 expression following brain injury resulting in hypoxia/ischemia.

Title: Rescue of visual function resulting from mitochondrial defects

Authors: *G. CORTOPASSI[1], S. DATTA[2], A. YU[2];
[1]VM: Mol. Biosci., UC DAVIS, Davis, CA; [2]UC Davis, Davis, CA

Abstract: Inherited mitochondrial defects cause neurodegeneration of neurons with long axons. Leber's hereditary Optic Neuropathy (LHON) is an inherited mitochondrial orphan disease causing complex 1 deficiency and vision loss resulting from Retinal Ganglion Cell death. We characterized vision loss in an animal model of mitochondrial disease, the Ndufs4KO mouse with a severe defect in mitochondrial complex 1. Retinal ganglion cell defects were determined

by MultiElectrodeArray (MEA) recording, and Electroretinogram (ERG) recording, and had obvious defects from day 30 on. RNAseq analysis of retinas demonstrated an 'inflammatory wave' that was coincident with vision loss, and preceded Retinal Ganglion Cell loss. We took a repurposing strategy to identify potential LHON therapeutics. We identified a specific biochemical defect in LHON cybrids, i.e. deficiency in Complex 1-dependent ATP synthesis, and screened 1600 FDA/EMA approved drugs for protection. This screening identified ultimately 2 drugs that dose-dependently protect from the LHON-dependent complex 1 ATP synthetic deficiency. These 2 drugs appear to hit the same mitochondrial target, in that agonists of that target protect and antagonists block the ATP synthetic rescue. The two drugs were tested for benefit in the Ndufs4 model of LHON. The two drugs provided significant protection from vision loss as measured by visual cliff and Electroretinograms, and rescue from the retinal 'inflammatory wave' that coincides with complex 1-dependent functional visual loss and retinal ganglion cell death. These results suggest that a repurposing strategy can identify novel leads with potential benefit for LHON therapy. Yu et al., (2015) Mitochondrial complex I deficiency leads to inflammation and retinal ganglion cell death in the Ndufs4 mouse.

Title: Enhancing brain metabolism to restore functional connectivity and plasticity after TBI

Authors: *G. KRISHNA[1], Z. YING[1], L. F. F. ROYES[3,1], A. PAYDAR[2], N. G. HARRIS[2], F. GOMEZ-PINILLA[1,2];
[1]Dept. of Integrative Biol. and Physiol., [2]Dept. of Neurosurgery, UCLA Brain Injury Res. Ctr., Univ. of California, Los Angeles, CA; [3]Exercise Biochem. Laboratory, Ctr. of Physical Educ. and Sports, Federal Univ. of Santa Maria – UFSM, Santa Maria-RS, Brazil

Abstract: The post-TBI metabolic depression impairs the ability of neuronal circuits to comply with activity demands, limiting the success of rehabilitative strategies, particularly during the acute period of TBI, which is critical for athletes to return to play, or patients to engage in rehabilitation programs. Although most neurons survive mild or moderate TBI, they cannot operate efficiently, and this severely compromises brain function. Our paradigm is based on the

concept that TBI disrupts brain functional connectivity (fc), and that synaptic function and cell metabolism are underlying substrates of fc. We capitalize on the enhancing action of flavonoid derivative, 7,8-dihydroxyflavone (7,8-DHF, BDNF analog) on cell metabolism and synaptic plasticity to restore fc. We performed moderate fluid percussion injury (FPI) and 7,8-DHF (5 mg/kg, ip) was administered in animals receiving FPI with or without exposure to voluntary exercise. TBI resulted in disturbances in energy homeostasis markers (PGC-1α, COX II) and plasticity/growth (GAP-43, synaptophysin), concurrent with reductions in memory in Barnes maze. Treatment with 7,8-DHF or exercise ameliorated impairments in cognitive function and energy homeostasis, and enhanced the activation of TrkB BDNF receptor signaling. The combined action of exercise and 7,8-DHF resulted in elevated values in most of the variables (in an additive fashion). Resting state functional MRI (rsfMRI) data acquired from the same groups to monitor circuit-level changes associated with functional brain reorganization showed that the action of 7,8-DHF improved brain circuit connectivity (nodal connection strength) compared to FPI alone, where it is was reduced compared to sham animals. Exercise and 7,8-DHF also normalized connectivity suggesting their potential to promote compensatory recovery of existing circuits. These data show that 7,8-DHF can render as a prototype molecule that links metabolism and synaptic plasticity, with the potential to normalize functional brain connectivity crucial to enhance the effects of training on TBI pathology. These findings further elucidate the functional implications of exercise and 7,8-DHF to provide novel perspective into neurorehabilitative strategy.

Title: Perivascular macrophages mediate vascular oxidative stress and neurovascular dysfunction induced by amyloid-β through CD36 and NOX2

Authors: *L. PARK[1], L. GARCIA-BONILLA[1], K. UEKAWA[1], P. ZHOU[1], R. PITSTICK[2], L. YOUNKIN[3], S. YOUNKIN[3], G. CARLSON[2], C. IADECOLA[1];
[1]Feil Family Brain and Mind Res. Inst., Weill Cornell Med. Col., New York, NY; [2]McLaughlin Res. Inst., Great Falls, MT; [3]Mayo Clin. Jacksonville, Jacksonville, FL

Abstract: Aβ has harmful effects on the cerebral microcirculation, which may contribute to cognitive impairment in Alzheimer disease and mixed dementias. The cerebrovascular effects of Aβ are mediated by reactive oxygen species (ROS) from a NOX2-containing NADPH oxidase activated by the interaction of Aβ with the innate immunity receptor CD36 (PNAS, 110:3089-3094, 2013). However, the cellular source(s) of the ROS have not been established. We tested the hypothesis that perivascular macrophages (PVM), myeloid cells located within the perivascular spaces and expressing CD36 and NOX2, contribute to the oxidative stress and cerebrovascular dysfunction induced by Aβ. Cerebral blood flow (CBF) was measured by laser-Doppler flowmetry in the somatosensory cortex of urethane-chloralose anesthetized male mice (age 3-4 months; n=5/group). PVM were depleted by icv injection of liposomes containing clodronate or PBS (vehicle), and tested its effect 7 days later. In mice injected with PBS liposomes, neocortical superfusion with $A\beta_{1-40}$ (5 μM) elevated ROS by 78±11% (Mean±SE; $p<0.05$) and attenuated the CBF increase produced by whisker stimulation (WS; -41±3%) or neocortical application of the endothelium-dependent vasodilator acetylcholine (ACh; -36±4%)($p<0.05$). PVM depletion (-60±4%) prevented oxidative stress and the attenuation in cerebrovascular responses both in WT mice treated with Aβ and in tg2576 mice ($p>0.05$ from controls). Since PVM are bone marrow (BM) derived, we used BM chimeras to delete CD36 or NOX2 in PVM. In WT mice transplanted with WT BM (wt-->◊wt), Aβ superfusion increased ROS in PVM by 80±8% ($p<0.05$) and attenuated CBF responses (WS: -32±2%; ACh: -24±3%; $p<0.05$ from vehicle). However, in WT mice receiving $CD36^{-/-}$ or $Nox2^{-/-}$ BM Aβ failed to increase ROS and to impair the CBF responses ($p>0.05$ from vehicle). Similarly, CBF responses were ameliorated in tg2576 mice receiving $CD36^{-/-}$ ($CD36^{-/-}$-->tg) or $Nox2^{-/-}$ BM ($Nox2^{-/-}$-->tg) ($p>0.05$ from wt-->◊wt), an effect associated with reduced vascular oxidative stress. Brain $A\beta_{1-40}$ levels did not differ between wt-->◊tg (4316±240 pmol/g) and $CD36^{-/-}$-->◊tg (3862±300 pmol/g) or $Nox2^{-/-}$-->◊tg (3781±313 pmol/g; $p>0.05$). We conclude that PVM are the critical cells required for the ROS production underlying the cerebrovascular dysfunction induced by Aβ, an effect mediated by CD36 and NOX2. These observations provide evidence that NOX2 and CD36 in PVM may be therapeutic targets to counteract the detrimental neurovascular effects of Aβ.

Title: Calpain 5, an overlooked calpain in CNS injuries

Authors: *J. W. GEDDES, V. BONDADA, C. MASHBURN, J. A. WANG, R. L. HILL, E. D. HALL, D. W. RODGERS;
Spinal Cord & Brain Inj Res. Ctr., Univ. Kentucky Med. Ctr., Lexington, KY

Abstract: Calpains are Ca^{2+}-activated, neutral proteases implicated in neurodegeneration following acute insults such as stroke and traumatic brain injury, as well as in neurodegenerative disorders such as Alzheimer's disease. Calpain research in the CNS has focused almost exclusively on the classical calpains, Calpains 1 and 2. Calpain 5 (CAPN5), which lacks the penta-EF hand domain of classical calpains, is highly expressed in the CNS. Calpain 5 has homology to other calpains in the cysteine protease domain and also has a unique C2 domain at the C-terminus. Many, but not all, C2 domains act as Ca^{2+}-sensitive enzyme activators, and are also involved in binding to membranes and protein-protein interactions. The only other mammalian calpain with a putative C2 domain is CAPN6, which is non-catalytic. CAPN5 is difficult to detect in the cytosol, but is found in nuclear and crude mitochondrial fractions. It is Ca^{2+} activated, as demonstrated by loss of activity following incubation with EGTA and mutation of the Cys residue at the active site. CAPN5 is activated for up to 72h following traumatic brain injury in rats (controlled cortical impact, 2.2 mm depth, 3.5 m/sec), resulting in enzyme autolysis. To determine if the putative CAPN5 C2 domain binds Ca^{2+} and participates in enzyme activation, we first identified possible Ca^{2+} binding sites by structural modeling then mutated the Glu/Asp residues and examined activity of recombinant human CAPN5 in stable cell lines. Modeling revealed that the C2 domain of CAPN5 is similar to that of extended synaptotagmin 2 and contains two putative Ca^{2+} binding sites, Asp431 and Asp589, as well as a Glu residue (590) which may facilitate Ca^{2+} binding. A single mutation, D589N, markedly reduced CAPN5 activity and also altered CAPN5 localization. Together, these results demonstrate that the CAPN5 C2 domain binds Ca^{2+}, contributes to enzyme activation, and influences localization. Based on its high CNS expression, and activation following acute insults such as TBI, CAPN5 must be considered along with classical calpains 1 and 2 when evaluating the roles of calpains following neurotrauma and other CNS disorders.

Title: Omega-3 fatty acids influence the onset and course of PTSD-like brain and behaviors following mild traumatic brain injury

Authors: A. OBENAUS[1], I. ALICEA-POLANCO[2], E. HADDAD[1], P. KALYAN-MASIH[2], J. D. VEGA-TORRES[2], E. KINNEY-LANG[1], M. DE LEON[2], *J. D. FIGUEROA[2];
[1]Pediatrics, [2]Ctr. for Hlth. Disparities and Mol. Med., Loma Linda Univ. Sch. of Med., Loma Linda, CA

Abstract: There is now substantial evidence that mild traumatic brain injury (mTBI) increases the risk of developing post-traumatic stress disorder (PTSD). Although the mechanisms by which risk of PTSD may be increased following mTBI remain unclear, it has been hypothesized that disruption of hippocampal homeostasis following injury may exacerbate PTSD symptoms. Omega-3 polyunsaturated fatty acids (n-3 PUFAs) are potent regulators of hippocampal function and have emerged as promising therapeutic agents for mTBI. The present study: (1) examines the efficacy of n-3 PUFAs to ameliorate PTSD-like behaviors at 4 and 8 weeks following mild controlled cortical impact (CCI) TBI in adult rats; (2) evaluates the impact of dietary n-3 PUFAs on hippocampal structure following chronic mTBI; (3) investigates the impact of omega-3 supplementation on hippocampal glucocorticoid signaling. Rats were fed with either control chow or chow enriched with n-3 PUFAs (750 mg/kg/day) for 4 weeks before being subjected to a single mTBI. We used a controlled cortical impact (CCI; 4 mm diameter tip, 0.5 mm depth, 6.0 m/s speed, 200 ms dwell) to induce mTBI. Animals were allowed to survive for 8 weeks after trauma and the brains collected for high-resolution magnetic resonance imaging (MRI). We found that consumption of n-3 PUFA significantly ameliorated functional deficits in locomotion (CatWalk XT gait analyses), sensorimotor gating (pre-pulse inhibition; PPI), nociception (mechanical-conflict avoidance), and anxiety-like behaviors (open field and elevated plus maze) following mTBI. Magnetic resonance imaging (MRI) demonstrated that dietary n-3 PUFAs preserved hippocampal volume when compared to animals fed with the control chow at 8 weeks post-injury ($p < 0.05$). Western blot and immunofluorescence analyses revealed a significant interplay between n-3 PUFA consumption and the FK-506-binding protein (FKBP51) levels in

the hippocampus. Collectively, our study demonstrates that the pathophysiological responses associated with PTSD are ameliorated by n-3 PUFAs consumption following mTBI.

Title: Interleukin-2 monoclonal antibody(JES6-1) attenuates cerebral ischemic injury via modulating T cell activation

Authors: ***Y. ZHOU**[1], P. LI[2], L. WANG[2], W. YU[2];
[1]anesthesiology department, Renji Hosp., shanghai, China; [2]Renji Hospital, Shanghai Jiaotong Univ. Sch. of Med., Shanghai, China

Abstract: Background: Interleukin -2 can modulate effector T cells and regulatory T cells through different protein binding sites to have different effects. T lymphocyte infiltration within the central nervous system mediated immune inflammatory response to neuronal survival and long-term neurological function after cerebral ischemia. We therefore investigated the effect of Interleukin-2 mAb (JES6-1) attenuating post-ischemia inflammation and improving the long-term neurological function. Methods and Results: We used animal models for experimental brain ischemia as a paradigm of acute brain lesions and inject IL-2 mAb (JES6-1)2 hours after ischemia. We demonstrated that IL-2 mAb (JES6-1) administration decrease the lesion size 3 days after ischemia and improve neurological functions lasting out to 4 weeks. The neuroprotection also includes decreased infiltration of peripheral inflammatory cells into lesioned brain. IL-2 mAb (JES6-1) can upregulate the Treg cell amount in the early stage of ischemia. Conclusion: IL-2 mAb (JES6-1) regulates the activation status of T cells and protect against ischemia. It may serve as a potent target for further stroke treatment after acute phase by regulate the activation of T cells.

Title: Acute upregulation of bone morphogenetic protein 4 regulates endogenous cell response and glial reactivity following spinal cord injury

Authors: *C. HART[1], S. M. DYCK[1], K. T. SANTHOSH[1], D. MILLER[2], S. KARIMI-ABDOLREZAEE[1];
[1]Physiol. and Pathophysiology, [2]Pharmacol. and Therapeut., Univ. of Manitoba, Winnipeg, MB, Canada

Abstract: Activation of astrocytes is a hallmark of spinal cord injury (SCI) that plays a key role in endogenous repair processes after injury. Reactive astrocytes modulate the injury microenvironment by producing a plethora of inhibitory factors. In this study, we demonstrate that activated astrocytes influence the properties of neural stem/progenitor cells (NPCs) by upregulating bone morphogenetic protein 4 (BMP4). BMP4 is a well known morphogen in the developing CNS with an established role in modulating astrocyte differentiation. In a clinically-relevant model of compressive SCI in rats, we found that BMP4 is robustly upregulated in the acute phase of injury between 1 and 3 days post injury. The temporal upregulation of BMP4 is correlated with several key events in acute SCI including vascular disruption and blood-spinal barrier permeability as well as activation of endogenous precursor cells. To date, the role of BMP4 in acute SCI has remained largely unknown. NPCs, glia and endothelial cells were all shown to express BMP receptors, suggesting they are responsive to changes in BMP4 expression. Here, using complementary *in vitro* and *in vivo* approaches, we sought to unravel the ramification of BMP4 upregulation on the repair process in acute rat SCI. Our findings suggest that reactive astrocytes are a significant source of BMP4 *in vitro* in response to IL-1β+TNFα activation, but not to LPS or TGFB treatment. Interestingly, microglia decreased their BMP4 expression upon activation. NPCs treated with BMP4 significantly decreased their proliferation and predominantly differentiated into astrocytes. These effects were inhibited when BMP4 was co-treated with noggin, a natural neutralizer of BMP4, in a concentration-dependent manner. In cultures of reactive astrocytes, BMP4 itself did not seem to be a global activator of astrocytes as there was no effect on their pro-inflammatory cytokine or nitric oxide production. However, BMP4 remarkably increased the production of inhibitory chondroitin sulfate proteoglycans (CSPGs). We also found that endothelial cells increase their expression of BMPER (BMP

binding endothelial regulator) in the acute phase of SCI suggesting a link between astrocyte and endothelial activity after injury. In conclusion, our findings indicate that SCI-induced upregulation of BMP4 impacts several cell populations in the injured spinal cord, by inducing astrocyte differentiation of NPCs, CSPG production by reactive astrocytes and may have a role in modulating vascular endothelial cells through its interaction with BMPER. Accordingly, our findings identify a role for BMP4 in modulating repair mechanisms after SCI.

Title: Conserved mechanisms underlying MultiStem® cell therapy across neurological injury and disease

Authors: *B. T. LANG, S. A. BUSCH, R. W. MAYS;
Regenerative Med., Athersys, Cleveland, OH

Abstract: Over the past 20 years, off-the-shelf cellular therapies have steadily progressed through pre-clinical and clinical development for the treatment of neurological disease and injury. However, a full understanding of the mechanism of benefit is necessary to optimize therapeutic efficacy. Athersys, is developing MultiStem, a unique bone marrow derived allogeneic cell therapy based upon the proprietary MAPC® cellular technology, for the treatment of multiple disease indications including ischemic stroke. In order to evaluate conserved mechanisms of action underlying MultiStem treatment, Athersys and collaborators performed focused pre-clinical animal studies in models of CNS injury and disease. Based on the summation of these results, we hypothesize that MultiStem infusion alters the innate immune response via interactions with splenocytes. Detailed pre-clinical biodistribution studies have revealed that MultiStem homes primarily to the spleen, reside in the marginal zone and lead to a global decrease in inflammation. MultiStem therapy has been shown to decrease pro-inflammatory cytokines, increase anti-inflammatory cytokines and ultimately modify the splenocyte phenotype. We have observed a consistent Th2 type response following MultiStem infusion, consisting of increased T regulatory cells and “alternatively” activated (M2) macrophage/microglial phenotype across several neurological indications. Further, our recently completed double-blind, randomized, placebo-controlled Phase 2 safety and efficacy trial in

ischemic stroke has provided strong verification of these pre-clinical findings. Intravenous MultiStem treatment between 24-36 hours following ischemic onset not only provided sustained significant functional improvements at 1 year, but also significantly reduced both global pro-inflammatory cytokine levels and circulating T cells in the blood. Our studies have identified conserved mechanisms underlying immune-modulation leading to neuroprotection and ultimately recovery following MultiStem therapy.

Title: N-acetyl-l-cysteine reduces hypoglycemia-induced hippocampal neuronal death

Authors: *A. KHO[1], J. KIM[2], B. CHOI[1], M. SOHN[3], S. SUH[1];
[1]Dept. of physiology, Hallym Univ., Chuncheon, Korea, Republic of; [2]Dept. of Pharmacol. and Therapeut., Univ. of Manitoba, Winnipeg, MB, Canada; [3]Dept. of Nursing, Inha Univ., Incheon, Korea, Republic of

Abstract: Type 1 diabetic patients who attempt tight control of blood glucose levels via insulin or other blood glucose reducing agents are frequently at risk of experiencing severe hypoglycemia. Severe hypoglycemia, which occurs if blood glucose levels fall below 1mM (18mg/dL), can lead to seizures, loss of consciousness and death. Hypoglycemic neuronal cell death is not a simple result of low glucose supply to the brain, but instead results from a cell death process that is initiated by the reintroduction of glucose after 10-30 minutes period of glucose deprivation. Glucose reperfusion after severe and prolonged hypoglycemia promotes oxidative stress, neuronal death and cognitive impairment. Zinc, a biologically essential element

for brain function, is the second most abundant transition metal in our body following iron. Despite, it's essential and ubiquitous role in neuronal function, excessive zinc release from the presynaptic terminals and translocation into postsynaptic neurons may contribute to neuronal death under several disease conditions, such as prolonged epileptic seizure, stroke, traumatic brain injury and hypoglycemia. Accordingly, zinc chelation or vesicular zinc depletion reduces hypoglycemia-induced neuronal death. N-acetyl-L-cysteine (NAC), restores levels of neuronal glutathione (GSH), a potent antioxidant, by providing a cell permeable source of cysteine. NAC also acts as a zinc chelator that alleviates zinc-induced neuronal death processes in the brain. Thus, we hypothesized that NAC treatment can reduce neuronal cell death, not only by increasing GSH concentration but also via zinc chelation. To test whether NAC can reduce hippocampal neuronal death after severe hypoglycemia, we used an animal model of insulin-induced hypoglycemia and injected NAC (300mg/kg/day, *i.p*) for 1 week after hypoglycemia. Severe hypoglycemia was induced by intraperitoneal injection of human insulin (10 U/kg) and iso-electricity was maintained for 30 minutes. Fluorescence staining using FJB was performed to detect degenerating neurons in the hippocampus. One week after the hypoglycemia, the number of FJB (+) cells was increased compared to sham-operated rats. However, 1-week treatment with NAC reduced the number of FJB (+) cells in the hippocampus after hypoglycemia. To detect oxidative stress, we performed immunofluorescence using the 4HNE antibody. In the present study we found that NAC treatment after hypoglycemia significantly reduced oxidative stress compared to vehicle treated control rats. Therefore, NAC treatment may represent a potential tool for reducing hippocampal neuronal death after severe hypoglycemia.

Title: Effects of an acetylcholinesterase inhibitor, donepezil, on seizure-induced hippocampal neuronal death

Authors: ***J. JEONG**[1], B. CHOI[1], M. LEE[2], H. CHOI[3], H. SONG[2], S. SUH[1];
[1]Hallym Univ., Chuncheon, Korea, Republic of; [2]Kangdone Sacred Heart Hospital, Hallym Univ. Med. Ctr., Seoul, Korea, Republic of; [3]Hallym University, Col. of Med., Chuncheon, Korea, Republic of

Abstract: Epileptic seizures are short episodes of abnormal brain electrical activity - the presence of recurrent and unprovoked seizures is known as epilepsy. During epileptic seizure, the primary symptoms may include tonic-clonic movement or convulsions, accompanied by a loss of memory that may be short or sustained. Many survivors of severe epilepsy display delayed neuronal death and permanent cognitive impairment. Donepezil is acetylcholinesterase inhibitor that has been shown to be effective treatment agent for Alzheimer's disease, dementia and in ischemic or hypoxic settings. However, the role of donepezil on seizure-induced neuronal death remains untested. Thus, the present study sought to evaluate the therapeutic potential of donepezil treatment on seizure-induced neural injury. To test our hypothesis, we used an animal model of pilocarpine-induced seizure. Temporal lobe epilepsy (TLE) was induced by intraperitoneal (*i.p*) injection of pilocarpine (25 mg/kg) in male rats. Donepezil (2.5 mg/kg/day) was injected by gavage for 3 consecutive days before seizure and Fluoro -Jade B (FJB) staining was performed to determine the degree of hippocampal neuronal death. Counter to our original hypothesis, we found an increased number of FJB positive neurons in the hippocampus of donepezil treated animals, compared to those receiving vehicle alone. These results suggest that donepezil treatment may have detrimental effect on hippocampal neuronal survival after seizure, rather than beneficial effects. Caution is needed for using donepezil and other acetylcholinesterase inhibitors in epileptic patients. Keywords: Epilepsy, pilocarpine, neuron death, donepezil

Title: Protocatechuic acid reduces traumatic brain injury-induced neuronal death

Authors: *S. LEE, B. CHOI, S. SUH;
Col. of Med., Chunchen, Korea, Republic of

Abstract: Traumatic brain injury (TBI) is defined as damage to the brain resulting from external mechanical force, such as rapid acceleration or deceleration, impact, blast waves, or penetration by a projectile. A penetrating head injury occurs when an object pierces the skull and breaches

the dura mater, the outermost membrane surrounding the brain. Neuronal death begins to occur in the hippocampus immediately after the traumatic brain injury. Protocatechuic acid (PCA), one of the main metabolites of complex polyphenols, possesses several biological effects, including anti-apoptotic and anti-inflammatory activity. In addition, it has been reported that PCA exhibits protective effects against oxidative damage. Here, the present study aimed to evaluate the therapeutic potential of PCA on TBI-induced neuronal death. Traumatic brain injury was induced using a controlled cortical impact (CCI) model in rat. PCA (30mg/kg) was injected into the intraperitoneal space immediately after TBI. Neuronal death and oxidative stress were evaluated by Fluoro Jade-B (FJB) staining and 4-hydroxy-2-nonenal (4HNE) immunostaining 24 hours after TBI, respectively. Microglia activation was detected by CD11b immunohistochemistry in the hippocampus 1 week following TBI. The post-treatment with PCA decreased the number of degenerating neurons, oxidative injury and microglial activation in the hippocampus. These results suggest that PCA may have therapeutic potential for reducing traumatic brain injury-induced neuronal death. Keywords: Traumatic brain injury, Protocatechuic acid, Oxidative injury, Microglia

Title: Protective effects of potocatechuic acid on seizure-induced neuronal death

Authors: ***S. LEE**[1], B. CHOI[1], M. LEE[2], H. CHOI[3], H. SONG[2], M. SOHN[4], S. SUH[1]; [1]Dept. of Neurol., Hallym Univ., Chuncheon, Korea, Republic of; [2]Kangdone Sacred Heart Hospital, Hallym Univ. Med. Ctr., Seoul, Korea, Republic of; [3]Hallym University, Col. of Med., Chuncheon, Korea, Republic of; [4]Inha Univ., Incheon, Korea, Republic of

Abstract: An epileptic seizure is a transient episode of abnormal brain activity that disrupts normal brain function and can lead to lasting detrimental effects, including neuronal cell death. Protocatechuic acid (PCA), a type of phenolic acid, is a major metabolite of antioxidant polyphenols found in green tea. It has various effects on normal and cancer cells, both in vitro and in vivo and has been shown to have antioxidant and anti-inflammatory activity in vitro. PCA also reduces myocardial infarct size through inhibition of inflammatory response and platelet

aggregation. PCA is also reported to increase cell proliferation and inhibited apoptosis of neural stem cells. However, the effect of PCA on seizure-induced neuronal death in the hippocampus has not been evaluated. Thus, we tested the potential therapeutic effects of PCA on seizure-induced neuronal death in an animal model of pilocarpine-induced seizure, a common model for epilepsy. Seizure was induced by intraperitoneal (i.p) injection of pilocarpine (25 mg/kg) in adult male rats and PCA (30 mg/kg) was injected into the intraperitoneal space for three consecutive days after seizure onset. Neuronal injury and oxidative stress were evaluated at 3-day post-seizure. To confirm whether PCA increases neuronal survival and reduced oxidative injury in the hippocampus, we performed Fluoro-Jade-B (FJB) staining to detect neuronal death and 4-hydroxynonenal (4HNE) staining to detect oxidative stress after seizure. In the present study we found that PCA treatment reduced neuronal death and oxidative stress in the hippocampus, compared to vehicle-treated controls. Therefore, the present study demonstrates that PCA has therapeutic potential for preventing hippocampal neuronal death after epileptic seizure.

Title: Sphingosine 1-phosphate receptor 1 regulates retinal ganglion cell survival and axonal regeneration after optic nerve trauma

Authors: ***V. E. PERNET**[1], D. DALKARA[2], S. JOLY[1];
[1]Ophthalmology, Ctr. De Recherche Chuq/Université Laval, Quebec, QC, Canada; [2]Inserm UMR S968, Inst. de la vision- Sorbonne universités, UPMC université Paris 6, UMR S968-CNRS, UMR 7210, Paris, France

Abstract: Sphingosine 1-phosphate (S1P) is a bioactive sphingolipid involved in major physiological and pathophysiological processes such as angiogenesis, inflammation, tumorigenesis and neuronal development. In the present study, we used a classical optic nerve injury model in C57BL/6 adult mice to address the function of the S1P-Sphingosine 1-phosphate receptor (S1PR) axis in retinal ganglion cell (RGC) death and axonal growth. After optic nerve lesion, the immunofluorescent signal of S1PR1 on retinal cryosections was lower in axotomized RGCs than in intact mice. Silencing S1PR1 with an adeno-associated virus serotype 2 (AAV2) containing a shRNA specific to S1PR1 (AAV2.shRNA-S1PR1) exacerbated the loss of RGCs induced by optic nerve crush; the survival rate of β3Tubulin-labelled RGCs was decreased by 34% in retinae infected with AAV2.shRNA-S1PR1 compared with AAV2.GFP control treatment. In the optic nerve, S1PR1 silencing had an even more pronounced effect on the reduction of axonal sprouting after lesion; the number of growing axons was reduced by 68% in AAV2.shRNA-S1PR1-injected mice at 100 μm past the injury site relative to control animals. We then addressed the contribution of S1PR1 to the protective and regenerative effects of ciliary neurotrophic factor (CNTF). In this aim, the ShH10.CNTF virus was used to infect Müller glia and sustain CNTF delivery to RGCs. Strikingly, after CNTF stimulation, AAV2-mediated S1PR1 down-regulation caused a 31-% decrease in the density of surviving RGCs relative to control conditions obtained with AAV2.GFP/ShH10.CNTF. The most severe loss of RGCs occurred in the superior quadrant where the density of RGCs was decreased by 58% relative to control retinae. The knock-down of S1PR1 affected RGC survival but had no deleterious effects on axonal regeneration in the injured optic nerve. Together, our results suggest that S1PR1 is involved in the survival of retinal ganglion cells induced by CNTF but is not required for axonal regeneration after optic nerve trauma.

Title: Sirt1 regulates NG2 expressing progenitor proliferation after white matter injury

Authors: *B. JABLONSKA[1], M. GIERDALSKI[2], T. HAWLEY[3], M. CARTON[2], A. LICHAUCO[2], J. CABRERA-LUQUE[2], T. YUEN[4], D. ROWITCH[5], V. GALLO[2];

Abstract: Regenerative processes in brain pathologies require generation of distinct neural cell populations from endogenous progenitors. We have previously demonstrated a novel role of Sirt1 in oligodendrocyte progenitor cell (OPC) proliferation in the developing subcortical white matter (WM) induced by perinatal hypoxia (Hx). Sirt1 phosphorylation occurs at residue 47 [Sirt1 (ser47)] as a result of post-translational modifications of Cdk2 and Rb. We also found that Hif1α activation and NAD production occur simultaneously with enhanced OPC proliferation in WM. Here, we demonstrated that Sirt1 distribution after Hx is increased in NG2-expressing progenitors but not in $Mash1^+$ cells. Cellular analysis revealed no Hx-induced changes in the numbers of $Sirt1^+CC1^+$, $Sirt1^+GFAP^+$ and $Sirt1^+Iba1^+$ cells. Also, we further established a causal relationship between Hif1α activation, Sirt1 and Cdk2 in Hx-induced WM injury. Using $Cdk2^{-/-}$ (KO) mice, in which exons 4 and 5 were ablated, we found that Hx increased the number of $Hif1\alpha^+$ cells, as well as Sirt1 $(ser47)^+$ cells in WM. This indicates that Sirt1 is upstream of Cdk2. Furthermore, these data also demonstrate that Hx promotes Sirt1 phosphorylation through kinases other than Cdk2. Consistent with this interpretation, Western Blot analysis confirmed higher levels of Hif1α and Sirt1 (ser 47) after Hx in both WT and KO mice. Further analysis established a link between NAD and Sirt1 activation after Hx. Cultured cells from Nx and Hx WM were incubated in control medium (with EGF + FGF), as well as with NAD or NADH for 24 hours. Immunoprecipitation analysis demonstrated lower levels of acetylated Cdk2 after Hx in control untreated cultures, suggesting increased deacetylation of Cdk2. NADH did not alter the levels of deacetylated Cdk2, which were similar in Nx and Hx cells; however NAD dramatically upregulated the level of deacetylated Cdk2 after Hx, indicating that the increase of NAD observed after Hx promotes Sirt1 activation and Cdk2 deacetylation. Together, these results indicate that Sirt1 is a major Hif1α- and NAD-dependent mediator of Hx-induced NG2-exprssing OPC proliferation in WM, and that Sirt1 directly activates Cdk2.

Title: MMP inhibitor SB3CT reduces accumulation of chloride in injured neurons

Authors: *V. I. DZHALA, J. GLYKYS, K. STALEY;
Neurol., Massachusetts Gen. Hosp., Charlestown, MA

Abstract: Low intracellular chloride ($[Cl^-]_i$) is an important determinant of post-synaptic $GABA_A$-receptor mediated inhibition. This low $[Cl^-]_i$ is set by the Donnan equilibria between immobile extracellular and cytoplasmic anions in conjunction with homeostatic $[Cl^-]_i$ and volume regulation by the cation-Cl^- co-transporters. However, acute brain injuries including trauma and hypoxia-ischemia alters the Donnan equilibria, which results in cytotoxic edema, elevated $[Cl^-]_i$ and depolarizing GABA responses, leading to epileptogenesis. The mechanism of critical pathological changes causing post-traumatic $[Cl^-]_i$ accumulation remains unknown. One possibility is that injured, gliotic areas have altered extra- and intracellular macromolecular compositions, which may change the balance of Donnan forces that set $[Cl^-]_i$ and the polarity and magnitude of $GABA_A$-receptor activity. Matrix metalloproteinases (MMPs) are involved in the degradation of the extracellular matrix and regulation of neuronal cell death. These calcium (Ca^{2+})-dependent zinc (Zn^{2+})-containing enzymes may be targetable by inhibitors of MMPs. We therefore tested whether SB-3CT, a potent and selective inhibitor of MMP-2 and MMP-9, reduces neuronal $[Cl^-]_i$ accumulation after acute brain injury. Acute hippocampal slices from mice expressing the Cl^- sensitive fluorescent indicator Clomeleon were used as a model of severe traumatic brain injury. Two groups of slices were pre-incubated in control ACSF and in a solution containing 20 μM SB-3CT. High-resolution two-photon fluorescence imaging of neurons expressing Clomeleon was performed 0-200 μm below the slice surface. In both groups of slices, morphological features of acute neuronal trauma associated with the neural shear injury induced during slice preparation included swollen or shrunken cell bodies and dendritic dystrophy and varicosities, mostly in the superficial 0-50 um layer of slices. In the deep layers of the acute slices, the cell bodies of neurons were morphologically preserved and healthy. In two groups of slices, traumatized neurons were characterized by increased $[Cl^-]_i$ in the superficial layers. However, statistical analysis demonstrated significantly lower $[Cl^-]_i$ in the superficial layers (0-50 and 50-100 μm) of slices pre-incubated in SB-SCT. At depth of 100-200 μm, no significant difference was found between two means that enclose that comparison. Our results demonstrate that MMP-2 and MMP-9 inhibitor SB-3CT ameliorates trauma-induced increases in neuronal chloride that could be predicted from effects on Donnan forces. This may exert neuro-protective effects and reduce cytotoxic cerebral edema after brain injury.

Title: An integral membrane phospholipid phosphate phosphatase, PLPPR1, overcomes chondroitin sulfate inhibition and promotes plasticity

Authors: *C. AGBAEGBU[1], H. KATAGIRI[1], H. GELLER[1], P. YU[2];
[1]Developmental Neurobio., NIH\NHLBI, Bethesda, MD; [2]Jinan Univ., Guangzhou, China

Abstract: Phospho Lipid Phosphate Phosphatase-Related (PLPPR) proteins (PLPPR1-5), also termed plasticity-related genes (PRGs), are integral membrane proteins characterized by six transmembrane domains and are a subclass of the lipid phosphate phosphatase (LPP) superfamily. A quantitative phosphoproteomic screen designed to determine global phosphorylation changes in neurons in response to chondroitin sulfate proteoglycans (CSPGs), potent regulators of neural plasticity during CNS development and axonal regeneration post-injury, revealed PLPPR1 as a protein whose phosphorylation state was most altered by exogenous CSPG treatment. PLPPR1 has been shown to induce actin-rich membrane protrusions in cell lines and primary neuronal cultures independent of Cdc42 and Arp2/3 signaling. However, its endogenous function is unknown. Here, we report that PLPPR1 expression in neurons overcomes axonal outgrowth inhibition mediated by CSPGs. Furthermore, to elucidate the function of these proteins in vivo, we have generated a knock-out mouse line for PLPPR1. Investigation into the global changes in brain structures using 3D reconstruction revealed enlarged lateral ventricles in the PLPPR1 KO mice. Additionally, using Golgi staining, we discovered reduced cortical and hippocampal dendritic spine density in PLPPR1 KO mice as compared to PLPPR1 WT animals. In summary, our data indicates that PLPPR1 protein may modulate neuronal response to CSPGs and regulate neuronal spine density and therefore may mediate neural plasticity. These studies will further define the functional significance of the interplay between CSPGs and PLPPR proteins as well as contribute, not only, to a more comprehensive understanding of how neural plasticity is modulated but also provide an avenue of investigation to improve therapeutic strategies after injury to the CNS.

Title: Brain trauma disrupts peripheral metabolism and fructose potentiates these effects

Authors: *Z. YING[1], L. F. F. ROYES[1,4], G. KRISHNA[1], F. GOMEZ-PINILLA[1,2,3];
[1]Dept of Integrative Biol. and Physiol., UCLA, Los Angeles, CA; [2]Dept of Neurosurg., UCLA, LosAngeles, CA; [3]Brain Injury Res. Ctr., UCLA, Los Angeles, CA; [4]Ctr. de Educacao Fisica e Desportos, Univ. Federal de Santa Maria, Santa Maria, Brazil

Abstract: Traumatic brain injury (TBI) is a complex disorder responsible for high rates of morbidity and mortality. It is known that TBI disrupts brain metabolism and dysfunctional metabolism is an important limitation for coping with secondary injury and the healing process. We have initiated studies to determine the action of TBI on crucial aspects of peripheral metabolism that could, in turn, influence the brain pathology. Here we report that 1week moderate fluid percussion injury (FPI, 2.7 atm) decreased glucose tolerance ($p<0.05$), and levels of plasma insulin had an increasing trend. A subgroup of animal was exposed to fructose consumption for 3 weeks (15% w/v, 3wks) before FPI onset to determine the effects of a metabolic perturbation on TBI pathology. Fructose consumption potentiated the increase in plasma insulin level ($p<0.01$) and the decrease in glucose tolerance ($p<0.05$) in animals exposed to FPI, indicating that fructose exacerbates the disruptive effects of TBI on peripheral glucose regulation. However, consumption of fructose for 3 weeks in intact animals was insufficient to alter peripheral metabolism by itself. The current 3 weeks of fructose consumption also increased escape latency in the Barnes maze test ($p<0.01$) in animals exposed to FPI, but fructose by itself was not sufficient to alter latency in intact animals. We have previously shown that 6 weeks of fructose consumption significantly disrupts memory performance in the Barnes maze in intact rats (Agrawal et al., J Neurophysiol, 2012), and aggravates memory dysfunction after TBI (Agrawal et al, JCBFM, 2016). Our results show that the effects caused by TBI are not limited to the CNS, and that circumstances that compromise brain metabolic homeostasis exacerbate the pathophysiology of TBI. These data emphasize that a short period of fructose consumption poses a risk for the outcome of TBI, and that peripheral pathology is partially dependent on central dysfunction carried by TBI.

Title: Validation of lysophosphatidic acid as a target for patients with traumatic brain injury

Authors: J. WOJCIAK[1], N. SABBADINI[2], A. J. MORRIS[3], C. MORGANTI-KOSSMANN[4], A. PÉBAY[5], D. DEUTSCHMAN[2], *R. A. SABBADINI[1];
[1]Res. and Develop., Lpath, Inc., San Diego, CA; [2]Biol., San Diego State Univ., San Diego, CA; [3]Lexington Veterans Affairs Med. Ctr., Lexington, KY; [4]Monash Univ., Melbourne, Australia; [5]Univ. of Melbourne, Melbourne, Australia

Abstract: Lysophosphatidic acid (LPA) is a bioactive lipid which mediates a series of signaling events through specific G-protein coupled LPA receptors (LPARs). LPA is released from activated platelets, astrocytes, choroid plexus cells and microglia and is reported to play major roles in inflammatory processes. In the nervous system, LPA signaling system has been validated as a mediator of neuropathic pain, hydrocephalus. Brain LPA also promotes loss of integrity and opening of the blood brain barrier. Recently published work with traumatic brain injury (TBI) showed significant increase in the concentration of LPA in the cerebrospinal fluid (CSF) of both the Controlled Cortical Impact (CCI) injured rodents and severe TBI patients. Further, following neurotrauma, there is an upregulation of LPARs in both mouse and human brain and spinal cord. Using an established CCI injury model, our two independent intervention studies revealed that treatment with the murine anti-LPA mAb, Lpathomab, reduced edema and hemorrhage normally observed following TBI, and that Lpathomab was neuroprotective, significantly reducing the lesion volume by 40-50% using histological and MRI assessments and in a study where a delayed administration of a single dose of Lpathomab at 2 hours after CCI, resulted in substantial and significant effects on behavioral/functional readouts 10 weeks, suggesting long-term benefits of the treatment. These studies combined unequivocally corroborate the efficacy of the anti-LPA antibody in mitigating neuronal damage and improving behavioral responses in injured mice and suggest that LPA may be a good target for therapeutic intervention in the clinical setting. Consequently, we embarked clinical study where we also validated LPA as a potential therapeutic target in TBI patients by correlating LPA levels in the CSF with clinical scores of Glasgow Coma Scale (GCS), Injury Severity Scale (ISS) and Extended Glasgow Outcome Scale

(GOSE) scores. Levels of LPA in CSF distinguished patient groups having unfavorable (GOSE 1-4) or favorable outcomes (GOSE 5-8) at 6 months post-TBI. This data may identify a TBI patient cohort with higher LPA that would most likely benefit from anti-LPA intervention therapy. Lpath's Lpathomab has shown excellent safety and tolerability profiles in a Phase 1a safety trial with healthy human volunteers, positioning Lpathomab for clinical trials in a targeted TBI patient population where LPA levels are elevated.

Title: Injury-induced alterations in amygdala e/i balance: synaptic mechanisms

Authors: *H. METHENY[1], C. PALMER[2], A. COHEN[1,2];
[1]Children's Hosp. of Philadelphia, Philadelphia, PA; [2]Univ. of Pennsylvania, Philadelphia, PA

Abstract: Traumatic brain injury (TBI) affects approximately 3.8 million people annually in the U.S, with roughly 5.3 million people, or ≈2% of the U.S. population, suffering persistent TBI-related disability. Individuals that suffer a TBI exhibit an increased likelihood of developing an array of neuropsychological symptoms including anxiety, aggression and depression; which in turn lead to an increase in substance abuse, suicidality, and mortality rate among TBI survivors. Due to its integral role in the expression and regulation of emotion, dysfunction of the amygdala is hypothesized to contribute to the acquisition and/or expression of the neuropsychological symptoms of TBI. Our laboratory has previously shown brain injury-induced circuit-level dysfunction in the amygdala associated with deficits in an amygdala-dependent behavior in a mouse model of mild to moderate TBI (mTBI). In this study, we identify a potential mechanism underlying altered circuit function and connectivity of the amygdala following mTBI. Whole cell

voltage-clamp recordings of glutamatergic spontaneous excitatory post synaptic currents (sEPSCs) onto basolateral amygdala (BLA) pyramidal neurons demonstrated a significant decrease in the frequency of sEPSCs after mTBI. Furthermore, there was a significant decrease in lateral amygdala stimulation evoked excitatory post synaptic currents (eEPSCs), with no changes in evoked inhibitory post synaptic currents (eIPSCs) in BLA pyramidal neurons from brain slices of mTBI animals. Given that the recorded eIPSC is predominately composed of polysynaptic inhibition dependent on activation by glutamatergic neurotransmission, the absence of a reduction in eIPSCs corresponding to the decrease in eEPSCs suggests that brain injury selectively preserves or augments GABAergic inhibition in addition to decreasing glutamatergic excitation. Our findings demonstrate opposing shifts in excitation and inhibition, resulting in a disruption of the excitation/inhibition balance (e/i balance) within the amygdala after mTBI. Investigating the underlying mechanisms of amygdala dysfunction after TBI is crucial to the development of therapeutics aimed at ameliorating neuropsychological symptoms of TBI.

Title: Increased dentate gyrus net synaptic efficacy is not due to altered hilar evoked GABAergic transmission following mild traumatic brain injury

Authors: *K. A. FOLWEILER[1,2], H. METHENY[2], B. JOHNSON[2], A. COHEN[2,1];
[1]Univ. of Pennsylvania, Philadelphia, PA; [2]Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: The dentate gyrus (DG) is a crucial regulator of hippocampal excitability and is thought to act as a filter or gate of cortical input to the hippocampus. Dentate granule cell excitability, and thus the putative gating function, is largely controlled by diverse GABAergic interneuron populations many of which reside in the hilus. Traumatic brain injury is known to cause dentate granule cell hyperexcitability, thereby compromising DG gating. Here, we used voltage-sensitive dye imaging (VSDi) with the voltage sensitive absorbance dye (di-3-ANEPPDHQ) to investigate the spatiotemporal characteristics of stimulus-evoked activity in the

dentate gyrus after injury, and potential alterations in hilar GABAergic interneuron evoked transmission that may contribute to net dentate synaptic efficacy. Hippocampal-entorhinal cortex (HEC) slices were made from male C57/BL6 mice 1 week following lateral fluid percussion injury (LFPI, 1.5 atm) for examination with VSDi. In response to perforant path electrical stimulation, all cell layers of the dentate gyrus (molecular layer, granule cell layer, and hilus) had significantly higher optical signals in slices from animals that underwent LFPI versus sham controls. Additionally, optical signals in area CA3 were increased after LFPI, suggesting enhanced propagation or spread of DG excitability to area CA3 after injury. To isolate hilar interneuron GABAergic transmission, the hilus was electrically stimulated in the presence of glutamatergic antagonists and evoked VSDi optical responses were recorded. The results demonstrate no significant difference in the optical signals between LFPI or sham slices in either the granule cell or molecular layers where these GABAergic interneurons are known to synapse onto granule cells. Overall, these data suggest that DG hyperexcitability does propagate to CA3 and that alterations in hilar-derived, evoked net inhibition do not contribute to this phenotype following experimental traumatic brain injury.

Title: Effects of traumatic brain injury and branched chain amino acid dietary therapy on spatial episodic-like memory

Authors: ***A. S. COHEN**[1,3], H. METHENY[2], G. XIONG[2], R. PATERNO[3];
[1]Div. Neurosci, [2]Children's Hosp Philadelphia, Philadelphia, PA; [3]Univ. of Pennsylvania, Philadelphia, PA

Abstract: Traumatic brain injury (TBI) can lead to significant cognitive impairment, however the underlying neurological basis for TBI-induced cognitive dysfunction remains unknown. Many lines of research have implicated the hippocampus in the pathophysiology of traumatic brain injury. Furthermore, it has been demonstrated that the hippocampus plays a key role during

episodic memory. However, specific impairments of spatial memory as a component of episodic-like memory after TBI have yet to be demonstrated. Here, we tested the putative effects of TBI on spatial memory (a component of episodic memory) while animals were performing a spatial recognition task. To test the association of TBI and spatial memory dysfunction, we used the lateral Fluid Percussion Injury mouse model of TBI together with a spontaneous novelty exploration task. The task used 3 different interval delays (3 minute, 1 hour and 24 hours) between familiarization and test phase of the task. We found that TBI animals exhibited significantly impaired discrimination only after 1 h and 24 h delays of old versus new spatial locations compared to Sham control animals. To further investigate how brain injury alters spatial memory and to investigate a possible therapy to improve this cognitive dysfunction, we administered dietary therapy consisting of branched chain amino acids (BCAAs) leucine, isoleucine and valine initiated 48 hours after the injury and maintained for 5 days in brain injured mice. We tested spatial memory and quantified ipsilateral hippocampal BCAA levels in animals on BCAA therapy. TBI animals exhibited decreased ipsilateral hippocampal BCCA concentrations compared to levels quantified in Sham control animals and a restoration to normal levels in injured animals on dietary therapy. Injured animals on BCAA therapy also demonstrated an improvement in spatial memory after 1h delay interval in BCAA group compared to TBI animals. These findings indicate that TBI impairs spatial memory after a longer compared to a shorter delay interval, and demonstrated the potential benefit of a possible therapy to improve this cognitive dysfunction.

Title: Hyperglycemia increases basal and swelling-induced ROS production in C6 cells

Authors: A. K. EDUAFO[1], N. A. SEITZ[1], G. LI[2], C. A. WAKER[1], *J. E. OLSON[2,1];
[1]Neuroscience, Cell Biology, and Physiol., Wright State Univ., Dayton, OH; [2]Dept Emergency Med., Wright State Univ. Boonshoft Sch. Med., Dayton, OH

Abstract: Diabetic ketoacidosis (DKA) is a potentially fatal hyperglycemic crisis which can leave survivors with permanent neurological sequelae. Brain edema occurs in 0.5-1% of DKA episodes in children with a mortality rate of 21-24%. In survivors, edema during DKA is associated with decreased mental status and poor clinical outcome. Oxidative stress is seen in a

variety of organs of diabetics and may be a common mechanism of tissue injury in this condition. Additionally, increased production of reactive oxygen species (ROS) occurs in many cell types during osmotic swelling. To explore the potential role of oxidative stress for brain injury in DKA, we quantified levels of ROS production in a rat brain cell line following hyperglycemia and during osmotic swelling. Rat C6 glioma cells were treated with hyperglycemic growth medium (26 mM glucose) for 24 hr. Control cultures received 5.5 mM glucose. Basal ROS production rates were measured with quantitative fluorescence imaging by perfusing cells with isoosmotic (290 mOsm) phosphate-buffered saline (PBS) containing 10 µm dihydroethidium (DHE). After 15 min, the PBS was changed to hypoosmotic (200 mOsm) PBS made by reducing the concentration of NaCl but containing the same DHE concentration. The integrated fluorescence intensity of 5-7 individual cells in each microscope field was quantified using ImageJ. The rate of change in fluorescence was calculated for each cell and these values averaged for each coverslip. For some studies, the NADPH oxidase (Nox) inhibitor, 100 µM diphenyleneiodonium (DPI) or the electron transport inhibitor, 5 µM oligomycin plus 5 µM rotenone were added to the PBS solutions. In parallel experiments basal and electron transport-dependent oxygen consumption was measured in isoosmotic PBS. Basal rates of ROS production increased by 23±3% for cells treated with hyperglycemic medium. This difference in ROS production rate was not seen when oligomycin and rotenone was added to the PBS. The swelling-induced increase in ROS production was more than three-fold higher for hyperglycemic-treated cultures compared with control cultures but was inhibited by DPI for both growth conditions. Basal oxygen consumption decreased from 10.7±0.8 pMoles/(min mg protein) in control cultures to 6.8±0.9 pMoles/(min mg protein) in hyperglycemic-treated cells. Thus, the increase in basal ROS production due to hyperglycemic exposure is due to mitochondrial electron transport despite a decrease in basal respiration. ROS production in swollen cells via Nox also is enhanced following hyperglycemia. Both mechanisms would contribute to oxidative stress and may lead to brain cell injury in DKA patients with brain edema.

Title: Zinc chelation and Klf9 suppression additively promote long distance axon regeneration after optic nerve injury

Authors: *E. F. TRAKHTENBERG[1], Y. LI[1], Q. FENG[1], J. TSO[2], P. A. ROSENBERG[3], J. L. GOLDBERG[5], L. I. BENOWITZ[4];
[1]Neurosurg., [3]Neurol., [4]Neurosurg. and Ophthalmology, [2]Boston Children's Hospital, Harvard Med. Sch., Boston, MA; [5]Ophthalmology, Stanford Univ., Palo Alto, CA

Abstract: The inability of neurons in the central nervous system (CNS) to regenerate damaged axons, as well as the limited capacity of undamaged neurons to form compensatory connections, limits recovery from ischemic or traumatic injury in the CNS. Manipulation of various cell-autonomous factors and/or overcoming cell-extrinsic inhibitors of growth in the adult CNS only partially restore regeneration and structural plasticity. Thus, the failure of CNS axons to regenerate after injury remains a major unmet problem. Here, we used a well-established optic nerve crush model in mice to traumatically injure and disrupt the axons of retinal ganglion cells (RGCs) in the optic nerve in order to test combinatorial effects of pro-regenerative treatments. We found that co-treatment with intravitreally injected zinc chelator, TPEN, and shRNA-mediated knockdown (KD) of the Klf9 transcription factor (via intraocular injection of an AAV2), had a much stronger effect than either one alone in promoting long-distance axon regeneration, enabling some axons to regenerate the entire length of the optic nerve in just 2 weeks. The growth factor oncomodulin combined with cAMP had about the same effects as either of the other two treatments, but did not strongly augment their effects. Co-treatment with TPEN and KLF9 KD conferred strong long-term protection on RGCs survival, elevating RGC survival ~7-fold higher than controls after 6 weeks. Furthermore, the effect of co-treatment with TPEN and KLF9 KD on long-distance axon regeneration persisted up to 6 weeks after injury, with some axons regenerating ipsilaterally through the optic chiasm and into the optic tract. Thus, zinc chelation in combination with Klf9 suppression additively promotes long-distance axon regeneration, and holds therapeutic potential for promoting axon regeneration after injury to the optic nerve and perhaps other parts of the CNS.

Title: Adaptaquin is an inhibitor of oxygen-sensing prolyl-hydroxylases that abrogates ATF4-dependent death and improves outcomes from brain injury

Authors: *S. S. KARUPPAGOUNDER[1], I. ALIM[1], M. W. BOURASSA[1], C. C. THINNES[2], T.-L. YEH[2], I. GAZARYAN[1], J. ZHONG[1], S. CHO[1], J. W. CAVE[1], C. J. SCHOFIELD[2], E. SHOHAMI[3], F. COLBOURNE[4], G. COPPOLA[5], R. R. RATAN[1];

Abstract: Disability or death secondary to brain injury is attributed to blood lysis, liberation of iron and the generation of oxidative stress. Iron chelators bind free iron and prevent neuronal death induced by oxidative stress, but the mechanisms remain unclear. Here we show that the hypoxia-inducible factor prolyl-hydroxylase (HIF PHD) family of iron-dependent oxygen sensors is an effector of iron chelation in abrogating brain hemorrhage. Molecular reduction of the three HIF PHD gene isoforms in the mouse striatum improved functional recovery following brain hemorrhage. Treatment with a low molecular weight, oxyquinoline inhibitor of the HIF PHDs, which we call *Adaptaquin,* reduced neuronal death and behavioral deficits following intracerebral hemorrhage in multiple rodent models. Adaptaquin also improved the cognitive function in a rodent model of traumatic brain injury. Unexpectedly, adaptaquin protects from oxidative death by suppressing ATF4-dependent prodeath gene expression rather than by activate the HIF-dependent prosurvival pathway or bulk iron chelation. Together these findings

identify Adaptaquin as a promising therapeutic agent for enhancing functional recovery following brain injury.

Title: The mGluR2/3 receptor antagonist BCI-838 reverses anxiety-related behavioral traits in a rat model of blast-related mTBI

Authors: ***G. PEREZ-GARCIA**[1], R. DE GASPERI[2,5], M. GAMA SOSA[2,5], M. LASHOF-SULLIVAN[6], S. AHLERS[6], G. ELDER[3,5], S. GANDY[4,5];

Abstract: Background: Blast-related mild traumatic brain injury (mTBI) has been a frequent effect of battlefield exposure to improvised explosive devices encountered during the conflicts in Iraq and Afghanistan. Elder and colleagues previously showed that rats subjected to repetitive low-level blast exposure displayed post-traumatic stress disorder (PTSD) related behavioral traits that were present many months after blast exposure (Elder GA, et al. 2012).
One consequence of TBI is reported to be impairment of neurogenesis, raising the possibility that proneurogenic drugs might be effective in modifying the course of latent manifestations resulting from mTBI. We have previously reported that pharmacological inhibition of the mGluR2/3 receptors with BCI-838 leads to pro-cognitive, and anxiolytic/antidepressant effects in rodents (Kim SH, et al. 2014). The aim of this study was to investigate whether administration of BCI-838 could enhance brain function and reverse PTSD-related behaviors in a rat model of blast-related mTBI.
Methods: Rats were subjected to three 75 kPa blast exposures under anesthesia. Starting two weeks after blast exposure they were treated daily with BCI-838 (4 and 10 mg/kg) for 2-months

and tested on a variety of cognitive and anxiety/stress related behavioral tasks.
Results: BCI-838 reversed anxiety in the open field, light/dark escape and zero maze compared to controls.
Conclusions: BCI-838 reversed anxiety-related behaviors in a rat model of blast-related mTBI and could represent a potential pharmacological therapy for veterans suffering from PTSD symptoms following blast-related mTBI.

Title: Changes in the pathology of head injury in mice with differing brain DHA levels

Authors: *A. DESAI[1,2], H. CHEN[2], K. KEVALA[2], H.-Y. KIM[2];
[1]Natl. Inst. On Alcohol Abuse and Alcoholism, Bethesda, MD; [2]Lab. of Mol. Signaling, Natl. Inst. on Alcohol Abuse and Alcoholism, Natl. Inst. of Hlth., Bethesda, MD

Abstract: Modern western diets have very low n-3 polyunsaturated fatty acid (PUFA) content and a high n-6PUFA to n-3 PUFA ratio. This is a matter of concern considering that brain levels of docosahexaenoic acid (DHA), a prominent n-3 PUFA, are dependent on the dietary intake of these PUFAs. Previously, we have demonstrated that mice with severe brain DHA depletion had impaired recovery after traumatic brain injury (TBI) compared to DHA-adequate mice. As severe DHA depletion is unlikely to occur in humans, we investigated in this study whether moderate brain DHA depletion affects the recovery outcome. E14 pregnant mice were placed on n-3 PUFA deficient diet and the pups were weaned on n-3 deficient or adequate diet to alter their brain DHA concentration. Controlled cortical Impact and Closed Head Impact Model of Engineered Rotational Acceleration (CHIMERA), a newly developed surgery-free model of head injury, were employed to induce TBI in these mice when they were 3.5-4 months old. For repeated head injury, the mice suffered one injury each day for three consecutive days. Mice supplemented with n-3 PUFA had higher level of DHA and lower arachidonic acid in the brain.

TBI caused an increase in glial cell activation along with behavioral deficits. The mice with more brain DHA had less injury-induced glial cell activation. A reduction in white matter injury was also observed in the adequate PUFA group. These changes in pathology were accompanied by a reduction in behavioral deficits in the mice that had more brain DHA as compared mice with less brain DHA. These findings indicate that dietary PUFA may play an important role in protecting the brain from the effects by increasing the resilience of the brain to injury.

Title: Inhibition of cysteine proteases, especially cathepsin B, improves behavioral deficits, pathology and biomarkers in traumatic brain injury and trauma-related animal models

Authors: *G. R. HOOK[1], S. JACOBSEN[2], K. GRABSTEIN[3], M. KINDY[4], V. HOOK[5]; [1]ALSP, Inc., La Jolla, CA; [2]iMed, AstraZeneca Neurosci., Cambridge, MA; [3]Dept. of Chem. Engin., Univ. of Washington, Seattle, WA; [4]Dept. of Pharmaceut. Sci., Univ. of South Florida, Tampa, FL; [5]Dept. of Neurosciences, UCSD, La Jolla, CA

Abstract: Polytrauma patients have elevated plasma cysteine protease activity, especially that of cathepsin B, and higher levels are correlated with increased risk of organ failure and death. Animal studies show that deleting the cathepsin B gene improves outcomes in traumatic brain injury (TBI) models and the trauma-related models of ischemia, chronic inflammatory pain, epilepsy, Alzheimer's disease (AD) and multiple sclerosis (MS). Here, data from various groups including our own are summarized showing that administration of small molecule cysteine protease inhibitors using various treatment regimes provides beneficial outcomes in a variety of TBI and TBI-related animal models. Specifically, inhibitor treatment of TBI animal models improves motor deficits and memory deficits while reducing brain lesion volume, neuronal cell death, apoptotic cell death proteins, including Bax, t-Bid, and mitochondrial cytochrome c, and inflammatory cytokines, including TNF-alpha and IL-1beta. Moreover, TBI-inhibitor studies using cathepsin B deficient animals show that most of the benefits obtained from inhibitor

treatment are due to cathepsin B inhibition. Inhibitor treatment of spinal cord injury models reduces gliosis, GFAP, and DNA fragments. In ischemic models, Inhibitor treatment provides potent neuroprotection by greatly lowering brain neuronal cell death, especially in the hippocampus. Inhibitor treatment of inflammatory pain models reduces pain and inflammatory cytokines, IL-1beta and IL-18. In epilepsy models, inhibitor treatment improves neurological scores and learning ability and eliminates pathological mossy fiber sprouting. Cerebral aneurysms and brain bleeding are major TBI complications and inhibitor treatment reduces motor sensory deficits, aneurysms, tissue loss, and neuronal cell death in those models. Edema is a big issue in TBI and inhibitor treatment of inflammatory edema models reduces edema, inflammatory pain, and necrosis. In transgenic AD mice, which overexpress human APP, inhibitor treatment improves memory deficits, increases long-term potentiation and, in some models, also reduces pathological amyloid plaque and Abeta peptides, including the pernicious pyroglutamate Abeta. MS model treatment results in improved clinical scores, increased age of onset, and reduced spinal cord leukocyte infiltration. Taken together, these data provide compelling evidence that small molecule inhibitors of cysteine proteases may provide significant benefits in the treatment of TBI patients.

Title: Apathy following traumatic brain injury increases with damage to the dopamine system

Authors: *P. O. JENKINS[1], N. BOURKE[2], S. DE SIMONI[2], D. J. SHARP[2];
[1]Computational, Cognitive and Clin. Neuroimaging Lab., [2]Imperial Col., London, United Kingdom

Abstract: *Background.* Apathy refers to a diminished level of motivation that is not the result of emotional distress, intellectual deficit, or a decreased level of consciousness. It is common following traumatic brain injury (TBI) and causes significant morbidity. Disruption to the dopamine system has been implicated in the causation of apathy in other neurological disorders (Sinha N et al., (2013) Cortex 49(5):1292-303; Mitchell RA et al., (2011) CNS Neurosci Ther 17(5):411-27). Therefore we explored whether disruption to the dopamine system following TBI is related to apathy.
Objective. To investigate whether striatal dopamine transporter (DAT) levels correlate with apathy following TBI.
Methods. 31 subjects who had suffered a TBI at least 6 months previously and had persistent cognitive problems were compared with 15 healthy controls. All subjects underwent an ioflupane (^{123}I) single-photon emission computed tomography (SPECT) scan and completed a Lille Apathy Rating Scale (LARS) (Sockeel et al., (2006) J Neurol Neurosurg Psychiatry 77(5): 579–584) as well as other behavioural questionnaires measuring depression and anxiety (the Hospital anxiety and depression scale), general health (Short form health survey) and fatigue (Visual analogue scale to assess fatigue). For 26 of the TBI subjects, we also obtained the LARS caregiver-based version to obtain an objective measure of apathy. SPECT scans were co-registered to high resolution T1 MRI scans and the Oxford-GSK-Imanova striatal atlas (Tziortzi et al., (2014) Cerebral Cortex 24(5):1165-77) was used to explore the relationship between the limbic, executive and sensorimotor subdivisions of the striatum to the apathy scores.
Results. Patients showed reduced striatal DAT levels compared to controls. Both subjective and objective apathy levels as measured by the LARS self and caregiver questionnaires showed a significant negative correlation with total striatal DAT levels. Within the limbic subdivision of the striatum DAT binding correlated negatively with the LARS caregiver but not self questionnaire. In contrast, DAT levels in the executive and sensorimotor sub-divisions correlated negatively with the LARS self but not the caregiver questionnaire. There was no significant correlation with the other behavioural questionnaires.
Conclusions. Apathy levels after TBI are higher in patients with evidence of reduced striatal dopamine. This suggests that a hypodopaminergic state may cause apathy after TBI and motivates an investigation of whether dopaminergic medications might improve this pervasive problem.

Title: Age-dependent effects of haptoglobin deletion in neurobehavioral and anatomical outcomes following traumatic brain injury

Authors: *A. V. GLUSHAKOV[1,2], R. A. ARIAS[3], E. TOLOSANO[5], S. DORE[4,2];
[1]Dept. of Anesthesiol., Univ. of Florida Col. of Med., Gainesville, FL; [2]Ctr. for Translational Res. in Neurodegenerative Dis., [4]Departments of Anesthesiology, Neuroscience, Neurology, and Psychiatry, [3]Univ. of Florida, Gainesville, FL; [5]Departments of Mol. Biotech. and Hlth. Sci., Univ. of Torino, Torino, Italy

Abstract: Introduction: Cerebral hemorrhages are common features of TBI and their presence are associated with chronic disabilities. Recent clinical and experimental evidenced suggest that haptoglobin (Hp), an endogenous hemoglobin-binding protein most abundant in blood plasma, would be involved in the intrinsic molecular defensive mechanism; though, its role in TBI is poorly understood. The aim of this study was to investigate the effects of haptoglobin deletion on the anatomical and behavioral outcomes in a mouse model of TBI.
Methods: The experiments were performed using controlled cortical impact model (CCI) in wild type (WT) C57BL/6 mice and genetically modified mice lacking Hp gene Hp-/- of the same background in two age cohorts [(2-4 mo old (young adult) and 7 8 mo old (older adult)]. Neurological deficit scores (NDS), activity and circling behavior were assessed at 24 and 48h, and brain pathology at 48h after injury using immuno- and histochemistry.
Results: The data obtained demonstrated age-dependent significant effects on the behavioral and anatomical TBI outcomes and recovery from the injury. Moreover, in the adult cohort, neurological deficits assessed as neurological deficit scores of Hp-/- mice at 24 h were significantly improved as compared to WT (P=0.001); whereas, there were no significant differences in brain pathology between these genotypes. In contrast, in the older adult cohort, Hp-/- mice had significantly larger lesion volumes compared to WT (P=0.0244), but neurological deficits were not significantly different. Immunohistochemistry for ionized calcium-binding adapter molecule 1 (Iba1) and glial fibrillary acidic protein (GFAP) did not reveal significant differences in microglial and astrocytic reactivity between Hp-/- and WT mice in both age cohorts.

Conclusions: The results of this study provide clarification on the age-dependent aspects of the brain trauma evident from the differences in anatomical and neurobehavioral outcomes between different age cohorts. Further, this this study provides an insight into the prospective roles of Hp in TBI and other acute brain injuries especially those with complex mechanisms suggesting that systemic Hp might age-dependently interact with the intrinsic defensive mechanisms involved in complex pathways and, thereby, differentially affecting acute brain trauma outcomes.

Title: Myelin plasticity supports recovery of nerve conduction velocity after experimental traumatic brain injury

Authors: *R. C. ARMSTRONG, C. M. MARION, N. P. CRAMER, K. L. RADOMSKI, F. YU, Z. GALDZICKI;
Dept Anatomy, Physiol. and Genet., Uniformed Services Univ. of the Hlth. Scienc, Bethesda, MD

Abstract: Patients with mild TBI (mTBI) often exhibit slow information processing speed which may indicate demyelination in white matter tracts. We used a mouse model of mTBI with traumatic axonal injury in the corpus callosum to examine myelin pathology and plasticity after mTBI. Functional integrity of myelinated axons in the corpus callosum was examined using electrophysiological recording in brain slice preparations from C57BL/6 mice after mTBI. Conduction velocity of the N1 myelinated axon waveform was significantly decreased at 3 days, consistent with demyelination. At 2 and 6 weeks the N1 conduction velocity recovered, suggesting remyelination may contribute to functional recovery. To monitor active remyelination in vivo after mTBI, we generated fluorescent myelin reporter mice. Conditional expression of Cre recombinase was driven in mature oligodendrocytes using PLPCreERT2 mice or in oligodendrocyte progenitor cells using NG2CreERT2 mice. Each driver line was crossed to mTmG reporter mice so that tamoxifen administration induced green fluorescent protein (GFP) labeling of membranes. Analysis of naïve PLPCreERT2:mTmG mice confirmed GFP labeled mature oligodendrocytes and myelin throughout the corpus callosum within 7 days of tamoxifen

administration. NG2CreERT2:mTmG mice were administered tamoxifen on days 2 and 3 post-mTBI to assess the progenitor response and EdU on days 3-7 to label cycling cells. At 7 days post-mTBI, NG2Cre mGFP labeling included cells with multiple short processes that were characteristic of progenitors and morphologically distinct from the myelin sheath labeling in PLPCreERT2:mTmG mice. A third of cycling EdU cells are also NG2Cre fate-labeled, though are only a small proportion of total NG2Cre fate-labeled cells. By 1 month post-mTBI, NG2Cre fate-labeled cells had matured into oligodendrocytes and elaborated myelin along axons. The corpus callosum area labeled with GFP myelin membrane was significantly greater in mTBI mice, relative to sham NG2CreERT2 mice, demonstrating remyelination after mTBI. Overall, mTBI produced demyelination resulting in functional deficits followed by remyelination and recovery.

Title: New therapeutic treatment for traumatic brain injury: targeting p75ntr as an immune-modulator after traumatic brain injury

Authors: *S. LEE[1], A. LIN[2], J. SACRAMENTO[2], N. SINGHAL[2], M.-N. CASTEL[3], B. CANOLLE[3], S. DELBARY-GOSSART[4], B. FERZAZ[3], F. BONO-COLOMBIE[4], J. C. BRESNAHAN[2], M. S. BEATTIE[2];
[1]Neurolog. Surgery, Brain and Spinal Injury Ctr., UCSF, San Francisco, CA; [2]UCSF, SF, CA; [3]Sanofi, Chilly-Mazarin, France; [4]Evotec, Toulouse, France

Abstract: Traumatic brain injury (TBI) patients often experience systemic immune suppression, causing high risk of infection and sepsis, and leading to poor clinical outcome after trauma. Indeed, TBI patients exhibit infections such as pneumonia, septicaemia, urinary tract infection, all of which result in high mortality. Thus, it is critical to counteract systemic immune

suppression in TBI patients. Although intuitively attractive, dampening systemic inflammation after TBI should be beneficial, however, it often results in very complicated outcomes. Therefore, it is important to broaden our understanding of the complexities of the inflammatory response following TBI to develop new and more specific therapeutic strategies for TBI patients. Myeloid derived suppressor cells (MDSCs) are a heterogeneous immature cell population, which have remarkable ability to suppress T cell function and to regulate innate immune responses by modulating cytokine production by macrophages. Indeed, trauma induces the infiltration of MDSCs into the spleen and subsequently suppresses T cell function, which is probably responsible for poor clinical outcome. However, their involvements in TBI have yet to be explored.
Here, we present for the first time that TBI results in the expansion of the MDSC population in the circulation, and subsequently, the accumulation of MDSCs in the injured brain as well as spleen, as evidenced by flow cytometry and immunostaining. Further, we have seen that TBI reduces the T-cell response signaling in the chronic spleen, which is critically related to immune susceptibility in chronic TBI. However, EVT901, a p75NTR antagonist, blocks the expansion of pro-inflammatory monocytes and MDSCs in the circulation, and inhibits the accumulation of these cells in the injured brain after TBI. Further, flow cytometric analysis indicated that EVT901 restores T cell function by reducing the accumulation of MDSCs in spleen chronically. Together, our data indicates that p75NTR is involved in the differentiation of the immature myeloid cell population into mature monocytes/macrophages in response to LPS and TBI, while EVT901 can regulate this. Altogether, our present data suggest that EVT901 can regulate the innate immune cell response by modulating differentiation of MDSCs and hence chronic immune suppression after TBI.

Title: Identification of targetable steps to modulate nNOS/NOS1AP(CAPON)-dependent signalling mechanisms

Authors: *L.-L. LI[1,2], M. JAAKKOLA[3], L. T. T. AN[3], L. L. ELO[3], M. J. COURTNEY[2]; [1]A.I. Virtanen Inst., Univ. of Eastern Finland, Kuopio, Finland; [2]Neuronal Signalling Lab,Turku Ctr. for Biotechnology, Univ. of Turku and Abo Akademi Univ., Turku, Finland; [3]Computat. Biomedicine Lab, Turku Ctr. for Biotechnology, Univ. of Turku and Abo Akademi Univ., Turku, Finland

Abstract: The protein NOS1AP (CAPON) is a mediator of signalling pathways downstream of the NMDA receptor/PSD95/nNOS complex. The nos1ap gene is linked to disorders from schizophrenia, post-traumatic stress disorder, and autism to cerebro- and cardiovascular disorders. Interaction between NOS1AP and nNOS regulates small GTPases, iron transport, p38MAPK-linked excitotoxicity, and anxiety. In recent years, NOS1AP-nNOS interaction emerged as a promising drug target in animal models of ischemia and anxiety. Understanding the mechanims of NOS1AP-nNOS interaction and NOS1AP function therefore has broad implications for numerous diseases and drug discovery. We find that the interaction of NOS1AP with nNOS differs radically from the classical PDZ docking previously assumed to be responsible. The NOS1AP PDZ motif has low affinity for the nNOS PDZ domain as measured by multiple methods. In contrast, full-length NOS1AP strongly interacts with nNOS. We find a novel internal region of NOS1AP that we call the ExF motif to be responsible for this discrepancy. Although the C-terminal PDZ motif is neither sufficient nor necessary for binding, it promotes the stability of the nNOS-NOS1AP complex. It therefore potentially affects signal transduction and suggests that functional interaction of nNOS with NOS1AP might be targetable at two distinct sites. We demonstrate that excitotoxic pathways can be regulated, in cortical neuron and organotypic hippocampal slice cultures from rats by peptides derived from ExF motif containing region. To better understand the regulation and function of nNOS-NOS1AP interaction, we developed a mathematical model to predict the generation of the active NOS1AP signalling complex. This model was based on experimentally determined values for the interactions between PSD95, nNOS and NOS1AP. A predictive model such as this may facilitate the identification of key steps in NMDA receptor-NOS1AP signalling most suitable for pharmacological intervention in NOS1AP associated diseases.

Title: Endogenous extracellular zinc is neuroprotective against glutamate excitotoxicity mediated via NMDA receptors

Authors: *R. F. KRALL[1], K. HARTNETT[2], T. TZOUNOPOULOS[3], E. AIZENMAN[2]; [2]Neurobio., [3]Otolaryngology, [1]Univ. of Pittsburgh, Pittsburgh, PA

Abstract: Zinc is an endogenous modulator of neurotransmission, notably through its inhibition of NMDA and AMPA receptors (NMDARs and AMPARs), and potentiation of glycine receptors (GlyRs).The majority of free zinc in the brain is loaded into vesicles by the zinc transporter Znt3, and co-released with glutamate. However there is an additional, Znt3 independent extracellular tonic pool of zinc that inhibits extrasynaptic NMDARs and potentiates GlyRs (Anderson et al., PNAS 112:E2705; 2015; Rosello et al., Neurobiol Dis 81:14; 2015). Because extrasynaptic NMDARs receptors are implicated in excitotoxicity (Parsons & Raymond, Neuron 82:279; 2014),we investigated whether the tonic zinc pool limits excitotoxic injury via its inhibition of NMDARs. To quantify tonic zinc levels, we used the extracellular ratiometric zinc probe LZ9. We measured nanomolar levels of extracellular zinc in rat mixed cortical cultures, similar to those measured in fresh brain slices of the dorsal cochlear nucleus. DL-threo-β-benzyloxyaspartate (TBOA; 75 μM), a glutamate transporter inhibitor, induced glutamate toxicity and caused a ~30% decrease in cell viability as measured by LDH cytotoxicity assays ($p < 0.05$). Chelation of endogenous extracellular $Zn2+$ with ZX1 (3 μM), a high-affinity extracellular zinc chelator, increased the toxicity of TBOA treatment, reducing viability to ~50% of control ($p <0.05$). In both cases, the NMDAR antagonist memantine (30 μM) blocked cell death. These results indicate that extracellular tonic zinc is neuroprotective via its inhibition of NMDA receptors.

Title: Zn^{2+} triggered mitochondrial dysfunction depends upon entry via the mitochondrial Ca^{2+} uniporter

Authors: *S. G. JI[1], J. H. WEISS[2];
[1]Anat. & Neurobio., [2]Neurology, Anat. & Neurobio., Univ. of California, Irvine, Irvine, CA

Abstract: Ca^{2+} and Zn^{2+} contribute critically to the induction of acute ischemic neurodegeneration. Zn^{2+} is released at synapses, where it can enter postsynaptic neurons. There are also intracellular pools of Zn^{2+} bound to buffering proteins, which can be released during ischemia. Prior studies have indicated that Zn^{2+} powerfully disrupts mitochondrial function, suggesting that these organelles may be important targets of its effects. Yet, despite this understanding, many pertinent aspects of Zn^{2+} effects on mitochondria remain elusive.
(1) Dependence of Zn^{2+} effects upon its uptake into mitochondria through the mitochondrial Ca^{2+} uniporter (**MCU**). While Zn^{2+} can enter the mitochondria via the MCU, past studies have been limited, in part by the incomplete specificity of MCU antagonists. With the recent identification of the MCU gene and availability of knockouts, we have confirmed the importance of this route and are examining whether mitochondrial Zn^{2+} effects are completely dependent upon uptake through the MCU, or despite diminished uptake, effects can still occur in its absence.
(2) Quantitative relationship between mitochondrial Zn^{2+} loading and its effects. Most prior studies have used high exogenous Zn^{2+} exposures to study the effects of mitochondrial Zn^{2+} accumulation, but the quantitative relation between mitochondrial loading and dysfunction has been little examined. One critical factor is that the amount of Zn^{2+} entry into mitochondria is highly dependent upon the efficiency of its cytosolic buffering, which is normally quite effective at protecting mitochondria from pathological Zn^{2+} loads. Using a combination of exogenous Zn^{2+} exposure and graded disruption of intracellular buffering, we are examining the "dose response" of Zn^{2+} uptake on a range of measures of mitochondrial function.
(3) Opportunities for intervention after Zn^{2+} loading to preserve mitochondrial function. We have found that interventions including Zn^{2+} chelation can diminish mitochondrial dysfunction after cellular Zn^{2+} loads, likely promoting their recovery. We are further examining this and other treatments (including MCU blockade) as well as determining the temporal window of opportunity to intervene after Zn^{2+} loading before dysfunction becomes irreversible.
Despite strong evidence that Zn^{2+} contributes to injury in conditions including ischemia, our

ability to target its deleterious effects for therapeutic benefit is limited. We hope that present *in vitro* studies will suggest new approaches for therapeutic interventions that we plan ultimately to test in more complex models.

Title: Nicotinic receptors neuroprotect rat hypoglossal motoneurons from excitotoxicity evoked by glutamate uptake block

Authors: S. CORSINI, M. TORTORA, *A. NISTRI;
SISSA, Trieste, Italy

Abstract: Amyotrophic lateral sclerosis (ALS) is a severe neurodegenerative disease characterized by progressive muscular paralysis due to bulbar and spinal motoneuron degeneration. There is, thus, a strong need to understand the earliest mechanisms of ALS onset and identify new treatments to arrest disease progression. In many ALS patients there are abnormally high levels of glutamate in the CSF because of decreased activity of the excitatory amino acid transporters 2 (EAAT2). This observation supports excitotoxicity as a key mechanism to damage motoneurons in the onset phase of this disease. To mimic this condition, we induced excitotoxicity in an established *in vitro* model of rat brainstem slices using the glutamate uptake blocker, DL-threo-beta-benzyloxyaspartate (TBOA). Brainstem hypoglossal motoneurons (HMs) are highly vulnerable to ALS because of their expression of calcium permeable AMPA receptors and low capacity to buffer intracellular free calcium. Activation of nicotinic acetylcholine receptors (nAChRs) by nicotine is reported to be a neuroprotective mechanism against certain experimental neurodegenerative diseases, neurodevelopmental disorders, and neuropathic pain; for this reason we investigated if nicotine could arrest the excitotoxic damage to HMs, which (together with premotoneurons) express homomeric alpha7 and heteromeric alpha4beta2 nAChRs. On 50% of patch-clamped HMs, sustained network bursting activity was induced by TBOA: bursting cells were most likely those that will later die. Nicotine (1-10 microM) increased inhibitory transmission and depressed synaptic excitation. When applied after TBOA-evoked bursting onset, nicotine, in a dose dependent manner,

decreased or even suppressed bursts. Conversely, nAChR antagonists facilitated bursting emergence in non-burster cells. We next studied how nicotine-mediated burst block could be related to HM survival. Thus, using MTT assay, immunohistochemical and RT-PCR experiments, we observed that prolonged exposure to TBOA (up to 4 h) induced 50 % loss of HMs, impaired energy metabolism, increased intracellular levels of reactive oxygen species (ROS), and upregulated genes connected with the endoplasmic reticulum stress. All these neurotoxic mechanisms were largely decreased or even prevented by coapplication of nicotine. Furthermore, these experiments revealed that nicotine *per se* was not toxic to HMs. Our results demonstrate significant neuroprotection of HMs by nAChR activity that are proposed as possible targets to mitigate the network hyperactivation and cellular distress caused by impairment of glutamate reuptake.

Title: General anesthetics regulate autophagy and cell survival via modulating inositol 1,4,5 trisphosphate receptor

Authors: G. LIANG[1], G. REN[1], Y. ZHOU[1], *D. J. JOSEPH[2], B. YANG[1], S. INAN[1], M. YANG[1], A. KING[1], H. WEI[1];
[1]Dept. of Anesthesiol. and Critical Care, Perelman Sch. of Medicine, Univ. of Pennsylvania, Philadelphia, PA; [2]Pediatrics Neurol., Children's Hosp. of Philadelphia, Philadelphia, PA

Abstract: General anesthetics provide dual effects of both cytoprotection and cytotoxicity with unclear molecular mechanisms. Here, we provide evidence that the commonly used general

anesthetics isoflurane and propofol control cell survival fate by regulating autophagy via activation of the type 1 inositol trisphosphate receptor Ca^{2+} release channel. An adequate exposure to general anesthetics induces autophagy in the mTOR dependent pathway and may be cytoprotective. In contrast, an excessive exposure to general anesthetics may impair normal autophagy flux and become cytotoxic, explaining anesthetics' exacerbating effect on Alzheimer's disease and high vulnerability of neurotoxicity in the developing brain. Thus, the effects of general anesthetics on apoptosis and autophagy are closely integrated, as both are caused by differential activation of the type 1 inositol trisphosphate receptor, which is involved in anesthetic mediated neurodegeneration in developing brain and in Alzheimer's disease.

Title: Trpc3 ion channel mediated calcium loading in mouse purkinje neurons

Authors: ***J. PARMAR**[1], A. J. CRAIG[2], M. KLUGMANN[2], G. VON JONQUIERES[2], L. BIRNBAUMER[4], A. J. MOORHOUSE[3], J. M. POWER[2], G. D. HOUSLEY[2];
[1]Translational Neurosci. Facility, Dept. of Physiology, Sch. of Med., UNSW Australia, Sydney, Australia; [2]Translational Neurosci. Facility, Dept. of Physiology, Sch. of Med., [3]Cell. and Systems Physiology, Dept. of Physiology, Sch. of Med., UNSW Australia, Kensington, Australia; [4]Inst. of Biomed. Res., Pontifical Catholic Univ. of Argentina (UCA), Buenos Aires, Argentina

Abstract: TRPC3 ion channels are non-selective cation channels that are coupled to mGluR1 in cerebellar Purkinje neurons (PNs) and mediate the slow excitatory post-synaptic current. Here, the genetically encoded calcium indicator GCamP5G was employed to dissect the contribution of TRPC3 ion channels to sustained mGluR-mediated Ca^{2+} loading, by comparing PN Ca^{2+} entry in brain slices from wildtype (WT) and TRPC3 knockout mice. All experiments were conducted with the approval of UNSW Animal Care and Ethics Committee. The cerebellum of TRPC3 null and WT (129SvEv) pups (P3) were injected with a recombinant adeno-associated virus (AAVrh10) driving GCamp5G expression under the control of the 1.1kb CMV enhancer/chicken

beta-actin promotor (CAG). At five to eight weeks, parasagittal cerebellar brain slices (400 μm) were imaged using a confocal microscope (Zeiss 710NLO LSM, 488 nm excitation; 10x/0.3W objective). Recordings were at room temperature with continuous superfusion of carbogen-bubbled bicarbonate buffer-based artificial cerebrospinal fluid (ACSF). MGluR1-mediated TRPC3 activation was achieved by bath application of (*S*)-3,5-Dihydroxyphenylglycine (DHPG,100μM) for 10 minutes. Slices were imaged every 10 seconds. ImageJ (NIH) was used to ascertain mean pixel intensity of individual PN somata. Changes in fluorescence (ΔF/F) were quantified as the fraction of evoked change in GCamP5G Ca^{2+} signal at the onset of DHPG application and 20 seconds before DHPG washout divided by the baseline fluorescence levels 2 minutes prior to DHPG application. These were compared between the TRPC3 null and WT slices. Activation of mGluR1 with DHPG increased PN florescence indicative of an increase in cytosolic Ca^{2+} levels. These GCaMP5G-mediated Ca^{2+} fluorescent signals were detected with a patchy distribution across the medial aspect of the cerebellar cortex. Fluorescent signal typically consisted of an initial peak followed by a sustained elevation in signal. In brain slices from TRPC3 null mice the amplitude of the initial transient Ca^{2+} fluorescent signal was reduced; average TRPC3 null PN $\Delta F/F = 0.47 \pm 0.12$ compared to average WT neuron $\Delta F/F = 1.15 \pm 0.43$; similarly for steady state DHPG responses TRPC3 null = 0.01 ± 0.02 vs WT = 0.35 ± 0.05 (3 brain slices from 2 WT mice and 5 brain slices from 3 TRPC3 null mice; range 3 to 14 PN analysed per field of view). These results support the concept that TRPC3 ion channels may contribute to ischaemic brain injury through sustained mGluR1- mediated Ca^{2+} influx. TRPC3 ion channel blockade in the PNs may thus provide a novel pathway to mitigate the detrimental effects of glutamate excitotoxicity by reducing Ca^{2+} loading of neurons.

Title: Control of excitotoxic injury by mitochondrial glutamate oxidation

Authors: A. S. DIVAKARUNI[1], M. WALLACE[2], A. Y. ANDREYEV[1], I. J. REYNOLDS[4], C. M. METALLO[2], *A. N. MURPHY[3];
[1]Pharmacol., [2]Bioengineering, UCSD, La Jolla, CA; [3]Pharmacol., UCSD, LA Jolla, CA;
[4]Discovery Res., Teva Pharmaceuticals, West Chester, PA

Abstract: Glutamate is the dominant excitatory neurotransmitter in the brain, but under the metabolic stress associated with epilepsy, stroke, traumatic brain injury, and Alzheimer's Disease, extraneuronal glutamate can rise to excitotoxic levels that exacerbates brain injury. The brain is heavily reliant on glucose as metabolic fuel, and slight reductions in glucose availability and oxidation are thought to have a profound impact on healthy brain function. Therefore, it was surprising to find that inhibition of the mitochondrial pyruvate carrier (MPC), an inner membrane transporter that facilitates pyruvate uptake from the cytoplasm into mitochondria, protects neuronal cultures from excitotoxic cell death.
Using a combination of bioenergetics, ^{13}C isotope tracing, and metabolomics, we find that mitochondria of cortical neurons readily use non-glucose substrates to fuel energetics and *de novo* glutamate synthesis. Because of this plasticity, MPC inhibition with UK5099 does not compromise neuronal viability or energy metabolism. Rather, mitochondrial metabolism is rewired to rely more heavily on glutamate to fuel energetics and anaplerosis in response to reduced pyruvate oxidation. The reduction in pyruvate oxidation increases glutamate oxidation and decreases the quantity of glutamate released upon depolarization, limiting the positive-feedback cascade of excitotoxic neuronal injury. Thus, MPC activity can influence the size of the releasable glutamate pool in neurons. The finding links pyruvate metabolism with glutamatergic neurotransmission, and establishes the MPC as a potential therapeutic target to treat neurodegenerative diseases characterized by excitotoxicity.

Title: Combined high throughput screening and high content analysis approaches to neuronal physiology/pathology monitoring provide powerful tools for drug discovery

Authors: *P. KITCHENER, L. PAULHAC, F. SIMON;
Fluofarma, Pessac, France

Abstract: Neuronal physiology is complex and its monitoring *in vitro* can include multiple types of measurements such as calcium homeostasis, cell membrane and mitochondrial membrane potential, survival, neurite network, protein expression and phosphorylation, and synaptogenesis. These parameters are dynamic over different time scales, and measurements rely on different technological approaches. They are often considered separately for drug discovery where relevant measures on a high number of test conditions require the miniaturization to small formats at a reasonable speed. As neuronal physiology is complex, drug screening using only one parameter for primary molecule selection can yield simplistic results when the most useful molecules already approved for CNS have complex profiles of action. We used rat primary cortical neuronal cultures in 384-well plates and combined the use of a high throughput fluorescent imaging plate reader (FlipR), for intracellular calcium and mitochondrial potential assessment, with live content imaging, to kinetically measure neuronal cell death, and endpoint high content imaging of neuritic parameters. Basal intracellular calcium measurements show true basal network properties in the primary cultures with spontaneous calcium oscillations confirming neurons are mature, functional and suitable for other measurements made in parallel. Excitotoxicity exemplified by NMDA receptor subtype stimulation, durably increases intracellular calcium concentrations over minutes, and triggers a loss of mitochondrial potential in less than an hour, followed by an increase of neuronal cytolysis over 12-20 hours, and a reduced viable neuritic network. The 384-well plate format allows for a simultaneous exploration of other glutamate receptor subtypes stimulation and multiple pharmacological treatments of the primary neurons yielding different results. Each treatment triggers different modifications of one, or several, of the measured parameters and a signature for each treatment can be derived by the parallel exploration of multiple parameters. The combination of technological approaches in neurons treated in parallel provides a continuum between measurements of fast short-term effects of test molecules (calcium homeostasis), to slow (mitochondrial membrane potential), and slower (neuronal cytolysis) consecutive events, in a dynamic, kinetic assessment of live cells. These dynamic measurements are complemented, at a relevantly chosen time point with the measurement of fine parameters in the same cells that were monitored by live content imaging, using immunofluorescence labeling with a vast array of possible targets.

Title: Structural disassembly of ATP synthase and its role in mitochondrial permeability transition during glutamate induced neuronal death

Authors: *N. MNATSAKANYAN, H. PARK, J. WU, P. MIRANDA, E. A. JONAS;
Dept. of Intrnl. Med., Yale Univ., New Haven, CT

Abstract: Prolonged exposure of neurons to glutamate triggers intracellular Ca^{+2} overload and induces the opening of the mitochondrial permeability transition pore (mPTP) during neurodegenerative diseases, traumatic brain injury and stroke. In addition to prolonged openings that occur under pathological conditions, transient openings of mPTP serve physiological functions. Despite many studies, the molecular components and the sub-molecular structure of the channel that forms the mPTP remain subject to scientific debate. We demonstrated recently that the membrane embedded c-subunit ring of the mitochondrial ATP synthase forms an uncoupling channel with the biophysical characteristics of mPTP. We show now that the F_1 catalytic portion of the ATP synthase gates the c-subunit channel and that mutations of specific amino acid residues within the channel reduce its conductance. We find that overexpression of wild-type but not low conductance c-subunit channels in primary hippocampal neurons exaggerates neuronal death under glutamate-induced excitotoxicity. We observe significant decrease in ATP synthase F_1 subunit levels during glutamate-induced toxicity, while levels of c-subunit remain unchanged. This suggests that structural disassembly of ATP synthase subdomains unmasks the pore of the c-subunit channel, placing mitochondria at increased risk for permeability transition. We present a novel structure-function model of mPTP gating by highlighting the molecular mechanisms and structural re-arrangements in ATP synthase necessary to open the c-subunit channel. These findings will provide us with increased understanding of the role of mPTP in aging and neurodegeneration.

Title: Iron overload-induced calcum signals modulates mitochondrial fragmentation in mouse hippocampal neuron cells.

Authors: *D. LEE[1], H. LEE[2], D.-S. LEE[1];
[1]Kyungpook Natl. Univ., Taegu-City, Korea, Republic of; [2]Biomed. Res. Institute, Chung-Ang Univ. Col. of Med., Seoul, Korea, Republic of

Abstract: Although iron is necessary for neuronal functions, excessive iron accumulation caused by impairment of iron balance damages to neurons. Neuronal iron accumulation has been observed in several neurodegenerative diseases, such as Alzheimer' disease and Parkinson's diseases. However, the precise mechanisms of iron toxicity in neuron cells are not fully understood. In this study, we investigated the mechanism of iron overload-induced mitochondrial fragmentation in hippocampal HT-22 neuron cells, which were incubated with ferric ammonium citrate (FAC). Mitochondrial fragmentation via dephosphorylation of Drp1(Ser637) and further apoptotic neuronal death were observed in FAC-stimulated HT-22 cells. Furthermore, the levels of intracellular calcium were increased by iron overload. Interestingly, chelation of intracellular calcium rescued mitochondrial fragmentation and neuronal cell death. Iron overload also activated the calcineurin through both Ca^{2+}/calmodulin and Ca^{2+}/calpain pathway. Moreover, the pretreatment of W13 and ALLN, as a calmodulin and calpain inhibitor respectively, attenuated iron overload-induced mitochondrial fragmentation and neuronal cell death. Therefore, these finding suggested that Ca^{2+}-mediated calcineurin signals are a key player in iron-induced neurotoxicity by regulating mitochondrial dynamics. We believed that our results may contribute to the development of novel therapy for neurodegeneration related with iron toxicity.

Title: Intracellular calcium ($[Ca^{2+}]_i$) regulating proteins as targets for chemotherapy in neuroblastoma

Authors: *D. BUSSELBERG[1], J. E. MCCALLUM[1], E. VARGHESE[1], N. GOPINATH[1], S. VARGHESE[1], A.-M. FLOREA[2];
[1]Weill Cornell Med. Col. In Qatar, Doha, Qatar; [2]Pathophysiologie, Univ. Düsseldorf, Düsseldorf, Germany

Abstract: Neuroblastoma is a cancer derived from sympathetic nerve cells occurring in infancy. Combinatory treatments are currently available, however, some patients at high-risk of tumor relapse can develop resistance to chemotherapeutic agents, limiting overall survival (<15%, 5-year). $[Ca^{2+}]_i$, a second messenger, mediates the regulation of intracellular signaling pathways related to cell-cycle progression, apoptosis and cell death. We investigate whether the chemotherapeutic treatment of a human neuroblastoma cell line (SH-SY5Y) alters the expression and function of calcium regulating proteins and if their pharmacological manipulation enhances the cytotoxic effect of chemotherapeutics such as cisplatin (CDDP) and topotecan (TOPO). We first employed a $[Ca^{2+}]_i$ sensitive fluorescent dye, Fluo-4-AM, to measure acute and sustained changes in $[Ca^{2+}]_i$ in SH-SY5Ys, following exposure to CDDP or TOPO (10nM-1uM) over 3h. The same concentrations were used to assess their effect on stages of cell death in SH-SY5Y cells via FACS analysis, at 72h. To assess expression levels of calcium regulating proteins, SH-SY5Y cells were stained with fluorescently conjugated antibodies targeting: IP3R1, IP3R3, RyR1, RyR3 and S100α6 proteins. These were imaged via confocal microscopy and quantified via "ImageJ" analysis, +/- 1μM CDDP or 10nM TOPO. Finally, 2-APB or dantrolene (IP3 and RyR receptor antagonists, respectively) were co-administered with CDDP or TOPO to assess their effect on cell viability, via trypan blue staining. Results demonstrate that both chemotherapeutic agents induce a time and concentration-dependent increase in $[Ca^{2+}]_i$ in SH-SY5Y cells. These concentrations promote significant late-stage apoptosis ($p<0.05$) and cell necrosis ($p<0.001$), following sustained exposure to either drug. Moreover, following 72h exposure, equivalent concentrations were also found to increase expression of IP3R3 ($p<0.001$), RyR1 ($p<0.001$) and S100α6 proteins ($p<0.05$) in SH-SY5Y cells. Whilst co-administration of IP3 and RyR antagonists exhibited a trend of enhanced chemotherapeutic cytotoxicity, the effect was only significant for the RyR blocker dantrolene in combination with TOPO in SH-SY5Y

cells ($p<0.001$). Data suggest a role for $[Ca^{2+}]_i$ in cytotoxicity and subsequent cell death of neuroblastoma cells, following exposure to therapeutic agents. The increased expression of calcium regulating proteins, such as RyR, following chemotherapy may warrant pharmacological manipulation to enhance $[Ca^{2+}]_i$ regulated cytotoxicity and subsequent cell death. Potentially, this may benefit high-risk patients with acquired chemotherapy resistance.

Title: Characterization of cross-resistance of cisplatin resistant neuroblastoma cells to other chemotherapeutic agents

Authors: *A. M. FLOREA[1], G. REIFENBERGER[2], D. BUSSELBERG[3];
[1]Heinrich Heine Univ. Düsseldorf, Uniklinikum, Düsseldorf, Germany; [2]Neuropathology, Heinrich-Heine Univ. Dusseldorf, Dusseldorf, Germany; [3]Weill Cornell Med. in Qatar, Doha, Qatar

Abstract: Neuroblastoma is a main cause of cancer-related mortality in children. Therapy of this childhood cancer is an immense challenge, in particular concerning effective treatment of high risk neuroblastoma patients who have a poor survival rate, often due to acquired drug resistance to conventional chemotherapy and consecutive tumor relapse. Acquired drug resistance commonly occurs upon chemotherapeutic treatment with standard anticancer drugs such as cisplatin (CDDP). In order to cope with drug resistance, new treatment strategies are required. In this study we investigated whether CDDP resistant neuroblastoma cells show cross-resistance to other anticancer drugs. We focused on the characterization of parental (CDDP sensitive) SH-SY5Y cells in comparison with CDDP resistant SH-SY5Y_R cells (resistant to 1µM). Cytotoxicity tests showed that chronic treatment of SH-SY5Y neuroblastoma cells with increasing concentrations of CDDP (up to 1µM) resulted in acquired CDDP drug resistance. The acquired drug resistance, however, was not specific for CDDP. i.e., we also detected cross-resistance to topotecan (TOPO) and taxol (TAXOL), but not to carboplatin (CBPL). We additionally tested if treatment of parental and CDDP resistant neuroblastoma SH-SY5Y cells

with two epigenetic modifiers, namely the (i) DNA methyltransferase inhibitor 5-aza-deoxycytidine (5-AZA) or (ii) the histone deacetylase inhibitor trichostatin A (TSA), may increase CDDP toxicity in neuroblastoma cells. The experiments demonstrated that TSA was much more effective in triggering cytotoxicity in neuroblastoma cells than 5-AZA.The treatment of 5-AZA alone had only a minor cytotoxic effect on SH-SY5Y neuroblastoma cells even at relative high concentrations (up to 200μM). Combinatory application with CDDP did not increase the effectiveness of chemotherapy. However, SH-SY5Y_R cells showed a cross-resistance to TSA treatment, i.e. TSA had a much weaker cytotoxic effect in the SH-SY5Y_R cells than in the parental SH-SY5Y cells. Overall, we observed cross-resistance to other anticancer drugs and epigenetic modifiers in neuroblastoma cells with acquired CDDP resistance. However, more research is necessary to investigate the mechanistic background of this phenomenon and to identify novel strategies for its modulation in both the experimental and clinical settings.

Sch. of Med., Tokyo, Japan

Abstract: Cordyceps militaris (CM), an herbal mushroom, has believed to be effective for various age-related disorders including the neurodegenerative disease, and its specific major bioactive component, cordycepin (3'-deoxyadenosine), appears more effective than CM. We administered 3% CM (JAPAN SILK BIO R&D CENTER) to Dahl salt-sensitive rats mixed with diet including 8% salt that reduced lifespan of these hypertensive rats, and also cordycepin

(0.1~10μM) to PC12 cells, and analyzed how CNS neurons and PC12 cells were influenced by these biochemicals with morphological, immunocytochemical and biochemical methods. CM increased lifespan (p=0.0001; ~3.3 (control) and ~4 (CM) months) of Dahl rats without reducing blood pressure and brain hemorrhage. CNS neurons including hippocampal pyramidal and Purkinje cells appeared degenerated, distensions of endoplasmic reticulum and Golgi apparatus with denser cytoplasm, in control rats, but normal in CM-treated rats. However, ATP synthase β subunit (β subunit), SIRT3, SOD2, LC3-II/LC3-I ratio, cathepsin D, and phosphorylated (p) AMPK were reduced in expression in CM-treated rats. In PC12 cells, we used naive or undifferentiated (tumorigenic in nature) and NGF-treated differentiated (neuronal in nature) cells. Cordycepin was harmful to undifferentiated PC12 cells, killing them, in a dose-dependent manner, without neurite outgrowth, but beneficial to differentiated cells with enhancing neurite extension and expressions of neuron-specific proteins, such as synaptophysin, MAP2 and neurofilament proteins. In undifferentiated cells, cordycepin enhanced expressions for β subunit, SOD2, LC3-II/LC3-I ratio, cathepsin D and pmTOR, but reduced those for SIRT1, SIRT3, pAMPK and pAkt. In differentiated cells, cordycepin enhanced β subunit, SIRT1, SIRT3, pAMPK and pAkt expressions, but reduced expressions for most of proteins enhanced in undifferentiated cells. CM extracts (0.1~10%) were also administrated to these PC12 cells, showing protein expression changes similar to those for cordycepin. In conclusion, CM may suppress AMPK activity in the brain neurons followed by declined mitochondrial/autophagic functions, retaining less cellular energy consumption associated with neuroprotection and lifespan extension after brain hemorrhage. Cordycepin may kill undifferentiated PC12 cells by activating mTOR through the inhibition of AMPK or Akt, which might be maintained by enhanced mitochondrial/autophagic functions, while it may promote neuroprotection in differentiated cells by the mechanism basically opposite to that for the undifferentiated cell, possibly similar to that proposed for the brain neuron.

Title: Korean red ginseng and ginsenoside-Rb1/-Rg1 alleviate experimental autoimmune encephalomyelitis by suppressing Th1 and Th17 cells and upregulating regulatory T cells

Authors: *M. LEE[1], M. JANG[2], J. CHOI[2], D. KIM[3], I.-H. CHO[2];
[1]Dept. of Convergence Med. Sci., Kyung Hee Uni., Seoul, Korea, Republic of; [2]Dept. of Convergence Med. Sci., Col. of Korean Medicine, Kyung Hee Univ., Seoul, Korea, Republic of; [3]Barrow Neurolog. Institute, St Joseph's Hosp. and Med. Ctr., Phoenix, AZ

Abstract: The effects of Korean red ginseng extract (KRGE) on autoimmune disorders of the nervous system are not clear. We investigated whether KRGE has a beneficial effect on acute and chronic experimental autoimmune encephalomyelitis (EAE). Pretreatment (daily from 10 days before immunization with myelin basic protein peptide) with KRGE significantly attenuated clinical signs and loss of body weight and was associated with the suppression of spinal demyelination and glial activation in acute EAE rats, while onset treatment (daily after the appearance of clinical symptoms) did not. The suppressive effect of KRGE corresponded to the messenger RNA (mRNA) expression of proinflammatory cytokines (tumor necrosis factor-α [TNF-α] and interleukin [IL]-1β), chemokines (RANTES, monocyte chemotactic protein-1 [MCP-1], and macrophage inflammatory protein-1α [MIP-1α]), adhesion molecules (intercellular adhesion molecule-1 [ICAM-1], vascular cell adhesion molecule-1 [VCAM-1], and platelet endothelial cell adhesion molecule [PECAM-1]), and inducible nitric oxide synthase in the spinal cord after immunization. Interestingly, in acute EAE rats, pretreatment with KRGE significantly reduced the population of $CD4^+$, $CD4^+$/IFN-γ^+, and $CD4^+$/IL-17^+ T cells in the spinal cord and lymph nodes, corresponding to the downregulation of mRNA expression of IFN-γ, IL-17, and IL-23 in the spinal cord. On the other hand, KRGE pretreatment increased the population of $CD4^+$/$Foxp3^+$ T cells in the spinal cord and lymph nodes of these rats, corresponding to the upregulation of mRNA expression of Foxp3 in the spinal cord. Interestingly, intrathecal pretreatment of rats with ginsenosides (Rg1 and Rb1) significantly decreased behavioral impairment. These results strongly indicate that KRGE has a beneficial effect on the development and progression of EAE by suppressing T helper 1 (Th1) and Th17 T cells and upregulating regulatory T cells. Additionally, pre- and onset treatment with KRGE alleviated neurological impairment of myelin oligodendrocyte glycoprotein35-55-induced mouse model of chronic EAE. These results warrant further investigation of KRGE as preventive or therapeutic strategies for autoimmune disorders, such as multiple sclerosis. Title: Involvement of activation of the Nrf2/HO-1 signaling pathway in protection against amyloid beta$_{25-35}$-induced neurotoxicity by sulfuretin

Authors: *S.-H. KWON[1], S.-Y. LEE[2], C.-G. JANG[2];
[1]Sch. of Pharm., Sungkyunkwan Univ., Suwon, Korea, Republic of; [2]Sch. of Pharm., Sungkyunkwan Univ., Suwon city, Korea, Republic of

Abstract: Sulfuretin, one of the major flavonoid glycosides found in the stem bark of *Albizzia julibrissin* and heartwood of *Rhus verniciflua*, is a known anti-oxidant. We previously demonstrated that sulfuretin inhibits neuronal death via reactive oxygen species (ROS)-dependent mechanisms in cultured cells, although other relevant mechanisms of action of this compound remain largely uncharacterized. As part of our ongoing exploration of the pharmacological actions of sulfuretin, we studied the neuroprotective effects of sulfuretin against amyloid beta (Aβ)-induced neurotoxicity in neuronal cells and investigated the possible mechanisms involved. Specifically, we found in the present study that sulfuretin significantly attenuates the decrease in cell viability, release of lactate dehydrogenase (LDH), and accumulation of ROS associated with Aβ_{25-35}-induced neurotoxicity in neuronal cells. Furthermore, sulfuretin stimulated the activation of nuclear factor erythroid 2-related factor 2 (Nrf2), a downstream target of phosphatidylinositol 3-kinases (PI3K)/Akt. We demonstrated that sulfuretin induces the expression of heme oxygenase-1 (HO-1), an anti-oxidant response gene. Notably, we found that the neuroprotective effects of sulfuretin were diminished by an Nrf2 small interfering RNA (siRNA), the HO-1 inhibitor zinc protoporphyrin IX (ZnPP), as well as the PI3K/Akt inhibitor LY294002. Taken together, these results indicated that sulfuretin protects neuronal cells from Aβ_{25-35}-induced neurotoxicity through activation of Nrf/HO-1 and PI3K/Akt signaling pathways. Our results also indicate that sulfuretin-induced induction of Nrf2-dependent HO-1 expression via the PI3K/Akt signaling pathway has preventive and/or therapeutic potential for the management of Alzheimer's disease (AD).

Title: Characterisation of dorsolateral prefrontal cortex microstructure following sodium azide induced Alzheimer's disease in rats: kolaviron therapeutic mechanisms

Authors: *O. J. OLAJIDE[1], O. B. AKINOLA[1], S. R. PRICE[2], B. U. ENAIBE[1];
[1]Anat. (Neuroscience Unit), Univ. of Ilorin, Ilorin, Nigeria; [2]Res. Dept. of Cell and Developmental Biol., Univ. Col. London, London, United Kingdom

Abstract: Evolvement of therapeutic targets following neurodegeneration is of major biomedical importance. Kolaviron (Kv) is a biflavonoid complex isolated from seeds of *Garcina kola* - a common oral masticatory agent in Nigeria known to hold medicinal value. Therefore this study evaluated the therapeutic potentials of Kv on cells of the dorsolateral prefrontal cortex (DLPFC), before or after sodium azide (NaN_3)-induced neurodegeneration. Rats were randomly assigned into 5 groups (6 each) and treated daily (orally) as follows: 1 ml of corn-oil (vehicle of Kv, 21 days); Kv only (200 mg/kg) for 21 days; NaN_3 only (20 mg/kg for 5 days); NaN_3 (20 mg/kg for 5 days) followed by Kv (200 mg/kg for 21 days); Kv (200 mg/kg for 21 days) followed by NaN_3 (20 mg/kg for 5 days). After treatments, exploratory behaviour associated with DLPFC function was assessed in the open field test (OFT). Subsequently, rats were sacrificed and perfused transcardially (4% PFA) with brains fixed in accordance of techniques demonstrated. Microscopic anatomy of the DLPFC was examined in histology (H & E), antigen retrieval immunohistochemistry to show astroglia activation (GFAP), neuronal metabolism (NSE), cytoskeleton (NF) and cell cycle dysregulation (p53). Furthermore, we demonstrated iNOS and nNOS by immunofluorescence while western blotting was used to investigate microtubule associated proteins (MAPT & MAP2) and apoptotic regulatory proteins (Bax, BCL-2 and CAD). Subsequently, we quantified the level of G-6-PDH and LDH in the brain tissue homogenate as a measure of neural tissue glucose metabolism patterns. Quantitative analysis was done using ImageJ software and statistical analysis with Graphpad prism (ANOVA) at $p<0.05$. NaN_3 treatment induced neuronal damage, characterized by reduced relative brain weight, pyknosis, karyorrhesis, astrogliosis, axonal/dendritic damages and cytoskeletal dysregulation that subsequently resulted in increased expressions of apoptotic regulatory proteins and behavioural alteration in OFT. These degenerative changes were relatable to the observed iNOS and nNOS upregulations. However, Kv administration attenuated the NaN_3-initiated destructive molecular cascades in the DLPFC of rats through mechanisms that involved inhibition of stressor

molecules and toxic proteins, prevention of stress related biochemical redox, preservation of neuronal integrity, protection of neuronal cytoskeletal framework and subsequently, reduced the level of apoptotic regulatory proteins which led to better OFT outcomes. We concluded that Kv conferred therapeutic benefits on NaN_3-induced neurodegeneration especially when administered before than after the damage.

Title: The neuroprotective effects and possible mechanism of action of a methanol extract from Asparagus cochinchinensis: *In vitro* and *In vivo* studies.

Authors: *A. JALSRAI[1], T. NUMAKAWA[2], H. KUNUGI[2], D. DIETERICH[3], A. BECKER[3]; [1]Ctr. of Traditional Med., Ulaanbaatar, Mongolia; [2]Dept. of Mental Disorder Research,, Natl. Inst. of Neuroscience, Natl. Ctr. of Neurol. and Psychiatry, Tokyo,, Tokyo, Japan; [3]Fac. of Med., Inst. of Pharmacol. and Toxicology, Magdeburg,, Germany

Abstract: Extracts of Asparagus cochinchinensis (AC) have antitumor, anti-inflammatory, andimmunostimulant effects. The neurobiological mechanisms underlying the effects of AC havenot been sufficiently explored. Thus we performed in vivo and in vitro experiments to furthercharacterize potential therapeutic effects and to clarify the underlying mechanisms.In the tail suspension test immobility time was significantly reduced after administration ofAC which suggests antidepressant activity without effect on body core temperature.Moreover, in animals pretreated with AC infarct size after occlusion of the middle cerebralartery was reduced. In vitro experiments confirmed protective effects. Total saponin obtainedfrom IT significantly inhibited H2O2-induced cell death in cultured cortical neurons. Such asurvival-promoting effect by AC saponins was partially blocked by inhibitors forextracellular signal-regulated kinase (ERK) and phosphoinositide 3-kinase Akt (PI3K/Akt)cascades, both of which are known as survival-promoting signaling molecules. Furthermore,phosphorylation of tyrosine phosphatase 2 (Shp2) was induced by AC, and the protectiveeffect of AC was abolished by NSC87877, an inhibitor for

Shp2, suggesting an involvementof Shp2-mediated intracellular signaling in AC saponins. Moreover, AC-induced activation ofpShp2 and ErK1/2 were blocked by NSC87877 inhibitor indicating that activation of thesesignaling pathways was mediated by the Shp-2 signaling pathway.These effects appear to be associated with activation of the Shp-2, ErK1/2 and Akt signalingpathways. Our results suggest that AC has antidepressant-like and neuroprotective (reducinginfarct size) effects and that activation of pShp-2 and pErK1/2 pathways may be involved inthe effects

Title: Curcumin inhibits the activation and translocation of NF-kB in rat hippocampus after experimental exposure to ozone

Authors: *S. D. NERY-FLORES, M. L. MENDOZA-MAGAÑA, M. A. RAMÍREZ-HERRERA, J. J. RAMÍREZ-VÁZQUEZ, M. M. J. ROMERO-PRADO, A. A. RAMÍREZ-MENDOZA, L. HERNÁNDEZ-HERNÁNDEZ;
Lab. de Neurofisiología, Dept. de Fisiología, CUCS, Univ. De Guadalajara, Guadalajara, Mexico

Abstract: *Background:* Ozone (O_3) is one of the major urban air pollutants. The exposure to O_3 leads to the formation of reactive oxygen species (ROS) which activate transcription factors, such as Nuclear Factor Kappa B (NF-κB). In turn, it induces the establishment of inflammatory processes. The hippocampus is highly sensitive to pathophysiological changes such as oxidative stress. NF-kB activation in glial cells (astrocytes and microglia) can indirectly induce neuronal death. NF-kB modulators, as curcumin (CUR), could reduce neuronal damage. The CUR has antioxidant, antiinflammatory, antimicrobial, antiproliferative properties, among others. Its various effects involve the regulation of different transcription factors, proinflammatory cytokines, growth factors and kinases. *Objetive:* This work evaluates the effect of curcumin on activation and translocation of NF-kB in rat hippocampus induced by exposure to ozone. *Methodology:* Fifty male Wistar rats were used (n=5 per group). The control groups were: intact, curcumin and ozone groups. The experimental groups were: the therapeutic group (diet with

CUR after exposure) and the preventive group (diet with CUR before exposure). The intact and curcumin groups were exposed to air stream free of ozone. The remaining groups were exposed daily to O_3 for 4 hours at a concentration of 0.7 ppm for 15 days for acute exposure or 60 days for chronic exposure. At the end of the exposure time, rats were sacrificed and the hippocampus was dissected, homogenate was obtained and the nuclear fraction was separated. To determine the activation and translocation of NF-kB was employed the electrophoretic mobility shift assay (EMSA). The groups were compared with the Kruskal-Wallis test followed by the U Mann-Whitney test. The significance level was set at $p<0.05$. *Results and conclusions:* Ozone control group presented a higher activation of NF-kB compared to the other controls groups ($p<0.001$). Dietary treatment with CUR in the preventive and therapeutic groups decreased translocation and activation of NF-kB ($p<0.001$) in animals exposed to O_3 and this effect occurred in the acute and chronic exposition. These results suggest that therapeutic and preventive dietary administration of CUR is capable of decreasing the activation and translocation of NF-KB after exposure to an oxidizing agent such as O_3.

Title: Mitochondrial targets of nobiletin and dieckol in the regulation of neuronal cell survival and death

Authors: J.-H. LEE, *S.-Y. EUN, J. WU, K. AMARSANAA, S.-C. JEON, S.-C. JUNG; Cheju Natl. Univ. Coll Med., Jeju-do, Korea, Republic of

Abstract: Mitochondrial calcium overload is a crucial event in determining the fate of neuronal cell survival and death, which is regulated by a variety of channels, antiporters and pumps, as well as an electron transport chains in the mitochondrial inner membrane. The regulation of mitochondrial calcium overload is considered to be an important strategy to prevent neuronal cell death. Therefore, we investigated here the mechanism of nobiletin and dieckol that inhibit neurotoxic mitochondrial calcium overload during neuronal insults.

Primary cortical neurons were obtained from the cerebral cortices of embryonic day 21 and postnatal 1 day Sprague-Dawley rats. Real-time optic measurements were performed using fluorescent indicators such as TMRE for $\Delta\Psi_m$, Fura-2 AM for cytosolic calcium, Rhod-2 AM for mitochondrial calcium and mitoSox/DCF-DA for mitochondrial reactive oxygen species (ROS) in primary cortical neurons. Mitochondrial calcium, ROS and $\Delta\Psi_m$ was also measured in the isolated mitochondria.The effects of neuroprotection were investigated using MTT cell viability assay.
The results demonstrated that nobiletin, an active compound of citrus peel extract, is able to evoke mild mitochondrial depolarization in both primary cortical neurons and isolated mitochondria, which is able to suppress mitochondrial calcium overload. Moreover, nobiletin-induced mild mitochondrial membrane depolarization was significantly abolished by 5-hydroxydecanoate (5-HD), a specific mitochondrial ATP-sensitive K^+ channel (mtK_{ATP}) blocker. In addition, nobiletin markedly reduced electron transport chain (ETC) complex I inhibitor rotenone-induced mitochondrial ROS generation, suggesting a possibility that complex I might be another mitochondrial target of nobiletin, besides mtK_{ATP}. Dieckol, one of the phlorotannins isolated from marine brown alga *Ecklonia cava*, strongly reduced neurotoxic mitochondrial calcium overload in dose-dependent manner.. The mitochondrial targets of diekol are being further investigated.
We propose that mitochondrial targets such as mtK_{ATP}, ETC complex I and mitochondrial calcium uniporter channels (MCU) may be implicated in the regulation of neuronal cell survival and death. Also, nobiletin and diekol as natural single compounds may be promising neuroprotective agents to prevent neuronal cell death through the regulation of the mitochondrial ion channel/transporter and ETC.

Title: Neuroprotective role of Thymoquinone in hippocampal cultures

Authors: *S. M. SHAIKH[1], M. S. RAO[2], S. SMITHA[2];
[1]Biotech., Dr. D.Y. PATIL BIOTECHNOLOGY & BIOINFORMATICS INST, Pune, India;
[2]Dept. of Anat., Fac. of Medicine, Kuwait Univ., Jabriya, Kuwait

Abstract: Thymoquinone (TQ), an active constituent of *Nigella sativa* seeds, possesses anti-inflammatory and neuroprotective properties. TQ is reported to enhance the neuroprotection in different CNS diseases and animal models of neurodegeneration. Aim of the present experiment was explore the efficacy of TQ in neuroprotection against kainic acid excitotoxicity on cultured hippocampal neurons. Primary culture of the hippocampal cells from the 18 days old embryonic hippocampus were grown for 7 days. These cultures were divided into control group (C), kainic acid group (KA), Kainic acid+Thymoquinone group (KA+TQ, n=6 in all groups). Control cultures continued to grow without any further treatment, KA cultures were exposed to media containing kainic acid (0.1μM) for 3hrs and thereafter continued to grow in the normal media for 1week. KA+TQ cultures were exposed to media containing kainic acid (0.1μM) for 3hrs and thereafter continued to grow in the media containing 0.1μM thymoquinone for 1week. Cell proliferation was assessed in all cultures during first 24hrs after commencement of treatment. Cell viability was assessed with MTT essay. Cultures were immunostained for doublecortin (DCX), Beta-3 tubulin (Tuj1) and glial fibrillary acidic protein (GFAP). Number of neurons (DCX and Tuj1positive) and glial cells (GFAP positive) were quantified in all cultures. Cell proliferation and cell viability were significantly increased in KA+TQ group compared to C and KA group ($p<0.01$). Thymoquinone treatment significantly increased the number of neurons in KA+TQ group compared to KA and C group ($p<0.01$). Number of astrocytes were also found to be significantly increased in KA+TQ group compared to KA and C cultures ($p<0.01$). The surviving neurons in the cultures treated with thymoquinone had larger cell bodies and longer processes. We conclude that Thymoquinone protects the neurons from kainic acid exitotoxicity, by increasing glial cell population.

Title: Comparison of the neuroprotective effects of phenolic acid metabolites of berry anthocyanins in cerebellar granule neurons

Authors: *E. IGNOWSKI, A. WINTER, M. BRENNER, M. SNODGRASS, D. LINSEMAN; Biol., Univ. of Denver, Denver, CO

Abstract: Neurodegeneration in specific areas of the brain is the primary cause of many devastating diseases such as amyotrophic lateral sclerosis, Alzheimer's disease, and Parkinson's

disease. Oxidative and nitrosative stress, along with excitotoxicity, have been implicated as major underlying factors in neuronal cell death. Nutraceuticals, bioactive compounds found in many fruits, vegetables, spices and herbs, have been shown to have neuroprotective effects in a variety of *in vitro* and *in vivo* disease models. Here, we compared the neuroprotective effects of two structurally similar nutraceuticals, 4-hydroxybenzoic acid (HBA) and protocatechuic acid (PCA), in primary cultures of cerebellar granule neurons (CGNs). These phenolic acids are major metabolites of the anthocyanins, callistephin and kuromanin, respectively, which are found at substantial concentrations in strawberries and blackberries. PCA differs from HBA only by the presence of a single phenolic hydroxyl group which provides PCA with a unique catechol moiety. Both HBA and PCA demonstrated significant protective effects against hydrogen peroxide-induced oxidative stress in CGNs. In contrast, only HBA rescued CGNs from excitotoxicity caused by glutamate. On the other hand, PCA uniquely protected CGNs from nitrosative stress induced by the nitric oxide donor, sodium nitroprusside. Finally, PCA also decreased nitric oxide production and tumor necrosis factor-alpha release elicited by lipopolysaccharide stimulation of BV-2 mouse microglial cells. The data suggest that the catechol moiety of PCA imparts a unique ability to counteract the toxicity of nitric oxide both in neurons and microglia. Due to their distinct neuroprotective profiles, HBA and PCA may be uniquely suited to treat different aspects of neurodegeneration. Future studies of the therapeutic potential of these compounds in preclinical models of neurodegeneration would be most beneficial if they compared the effects of individual and combined treatment with these phenolic acids on disease progression.

Title: Curcumin is able to reverse the inhibition of neurotransmitter release by beta amyloid oligomers at choroidal synapses in the embryonic avian eye.

Authors: J. QUINN[1], O. ANDERSON[2], M. RAJSOMBATH[3], *D. GRAY[4];
[1]Biol., [2]Neurosci. & Behavior, [3]Biochem., [4]Simmons Col., Boston, MA

Abstract: Alzheimer's disease (AD) is a prevalent neurodegenerative disease associated with characteristic senile neuritic plaques containing a fibrillar form of beta-amyloid (Ab) peptides. This lab has demonstrated a non-pathological role of a-beta as a possible neuromodulator at avian cholinergic synapses, decreasing acetylcholine (ACh) release by stimulating nitric oxide (NO) synthesis and subsequent synthesis of guanyl cyclase and protein kinase G, eventually leading to decreased exocytosis. Previous studies showed that a nitric acid donor (NOD) (1 uM (3,3-bisaminoethyl-1-hydroxy-2-oxo-1-triazene [NOC-18])) mimics Ab's regulatory effects on ACh release. A-beta's role in AD pathogenesis is also thought to involve NO, which is known to induce formation of inflammatory free radicals. Curcumin, a principle compound of turmeric, is well-described antioxidant known to reduce Ab toxicity. Previously curcumin has been hypothesized to act by disrupting aggregation of Ab peptides into an oligomeric form necessary for toxicity. This study demonstrates curcumin, at ~ 1 uM levels, is able to reverse inhibition of ACh release by Ab oligomers at avian embryonic choroid synaptic terminals, but rules out effects on Ab aggregation since curcumin is also able to reverse inhibition of ACh release by direct NO exposure which is downstream from Ab. Curcumin is not able to reverse the effect of cGMP on ACh release. This suggests that curcumin is acting at the nitric oxide step. Further experiments have determined that curcumin does not prevent the donor from producing NO, but rather blocking the nitric oxide effect. These results demonstrate that curcumin is involved in both the pathological and non-pathological pathways. Further research is underway to determine by what process curcumin can reverse nitric oxide's effects.

Title: Ceramide contributes to cognitive impairment and palmitate induced apoptosis in hippocampal cell culture

Authors: *C. WANG[1,2,6], T. A. BUTTERICK[1,2,6], V. MAVANJI[3], C. M. DUFFY[2], M. R. LITTLE[2], E. E. NOBLE[2], J. P. NIXON[1,2], C. J. BILLINGTON[1,4,6], C. M. KOTZ[1,5,6]; [1]Minneapolis VA Hlth. Care Syst., Minneapolis, MN; [2]Food Sci. & Nutr., Univ. of Minnesota, St. Paul, MN; [3]Food Sci. & Nutr., Univ. of Minnesota, St. Pau, MN; [4]Medicine, Food Sci. & Nutr., [5]Neuroscience, Integrative Biol. and Physiology, Food Sci. & Nutr., Univ. of Minnesota, Minneapolis, MN; [6]Minnesota Obesity Ctr., Minneapolis, MN

Abstract: Background: Obesity and consumption of diets high in saturated fats are important risk factors for cognitive impairment. Brain uptake of fatty acids is increased in conditions of metabolic syndrome and aging. In our previous study, feeding rodents a high fat diet impaired their learning. Ceramides, synthesized de novo from saturated palmitate, are increased in brain along with aging and Alzheimer's disease (AD), and an increased ceramide level has been suggested as a biomarker for mild cognitive impairment and AD. We hypothesize that ceramides contribute to hippocampal apoptosis induced by palmitate. Methods: *In vitro*, hippocampal cells were treated with vehicle, myriocin (an inhibitor of de novo ceramide synthesis, 100 nM), palmitate (0.1 mM), or myriocin + palmitate; and measured for cell viability, pro-apoptotic signaling (caspase-3/7 and lipid pro-oxidant 4-HNE), and pro-survival signaling (Bcl-2, Akt and BDNF). Stable isotope [U-^{13}C]-palmitate was used to determine ceramide levels with GC/C/IRMS. We also measured the direct effect of artificial C2- and C6-ceramide (0.1~120 μM) on cell viability. *In vivo*, male Sprague-Dawley rats (nine-month old) were trained in memory tests with a two-way active avoidance paradigm, and given intraperitoneal (IP) injections of C6-ceramide (2 μg/kg) every other day for 28 days during which memory was monitored weekly. The data were analyzed with ANOVA or multivariate assay of general linear model. Results and Conclusions: *In vitro*, palmitate significantly reduced cell viability, Bcl-2, Akt and BDNF, and increased caspase 3/7 activity and 4-HNE; while addition of myriocin attenuated palmitate-induced cell death and caspase 3/7 activity. In parallel, the treatments significantly impacted ceramide (C14~24) production, specifically for C16-Cer which was more than 50% of the total ceramides measured. Palmitate increased C16-Cer by 84.8%, and 70% of the synthesized C16-Cer was from exogenous palmitate. Addition of myriocin greatly reduced C16-Cer by 73.3% vs. that of palmitate alone. Thus, elevated synthesis of ceramides might increase pro-apoptotic and reduce pro-survival signaling; while blockade of ceramide synthesis could reverse the pathways induced by palmitate/ceramides. Directly treating the hippocampal cells with C6-ceramide at 40 μM reduced viability and increased caspase-3/7 activity, supporting an apoptotic role of the ceramide. *In vivo*, learning impairment occurred at three-week of IP ceramide injections, indicated by increased escape latency and failure rates. In conclusion, ceramides contribute to palmitate-induced apoptosis of hippocampal cells and cognitive impairment.

Title: Understanding the effects of TDP43 C-terminal fragments

Authors: *Y. T. KASU, C. S. BROWER;
Biol., Texas Woman's Univ., Denton, TX

Abstract: Despite uncertainty surrounding the exact molecular cause of neurodegeneration, a defining feature is the accumulation and aggregation of neuronal protein fragments resulting from an increase in their production, or a decrease in their removal. Previously, we found that the N-end rule pathway of the ubiquitin-proteasome system is able to degrade specific protein fragments associated with Alzheimer's disease, Parkinson's disease, amyotrophic lateral sclerosis (ALS) and frontotemporal lobar degeneration (FTLD). This discovery suggests that defects in the N-end rule pathway may contribute to neurodegeneration. To determine if protein fragments play a causative role in disease, we are examining the ectopic expression of a specific aggregation-prone fragment of the human TDP43 protein ($TDP43^{247-414}$) that was found to be a major constituent in intraneuronal plaques found in patients with ALS and FTLD. $TDP43^{247-414}$ was found to be degraded largely by the N-end rule pathway in a manner that requires the *ATE1*-encoded arginyl transferase. We show that $TDP43^{247-414}$ accumulates in Neuro2a cells and in the brains of mice that lack Ate1. Interestingly, $TDP43^{247-414}$ stabilization partially restored the reduced body weight phenotype seen mice lacking Ate1. Ultimately, these studies will help us to understand the effects of $TDP43^{247-414}$ accumulation on neuronal cell function.

Title: Chronic iron overload and deficiency in adult male c57b6 mice

Authors: *D. G. PETERS[1], J. R. CONNOR[2], Q. X. YANG[3], M. D. MEADOWCROFT[2]; [1]Neural and Behavioral Sci., [2]Neurosurg., [3]Radiology, The Pennsylvania State Univ. - Col. of Med., Hershey, PA

Abstract: Non-heme iron plays a crucial role for metabolic function within the brain and its regulation is tightly controlled. Increased brain iron levels are unique to humans, are two- to four-fold higher than murine brain tissue, and increase with age. This suggests that iron plays an associative role with the aging process and may influence the progression of neurodegenerative disease through oxidative stress, inflammation, and cell death. Conversely, iron deficiency dramatically impairs brain growth during development, but the impact of iron deficiency on the brain during adulthood has not been evaluated. The goal of this study was to evaluate chronic iron overload and deficiency in a C57B6 mouse model to assess how iron dyshomeostasis impacts neural response, brain morphology, and memory. We modeled iron load with four different diets over the course of 12 months beginning at 10 weeks old: Iron deficiency (2-3ppm Fe), Normal Control (200ppm Fe), 0.1% lipophilic TMH-Ferrocene (TMHF), and 0.5% TMHF. Longitudinal magnetic resonance image (MRI) metrics, plasma collection, and behavioral testing were acquired at three-month intervals. Brain morphology and proton relaxometry (R_2) alterations associated with dietary iron overloading were assessed. At study end, liver and segmented brain regions were collected to measure iron concentration, iron storage protein dynamics, and immuno-histological evaluation. Brain R_2 increased in regions known to store iron (substantia nigra and caudo-putamen) in all dietary groups within the first six months and gradually increased in the frontal cortex and the parietal cortex over the preceding six months. The MRI metrics were exacerbated in the ferrocene dietary groups and developed at three months; spreading into the hippocampus, parietal cortex, and cerebellum at 12 months. Deformation based morphometry revealed that there was an expansion of gray matter in the TMHF groups and expansion of white matter in the iron deficient group at 12 months. Gray matter regions were shown to have increased IBA1 and ferritin expression in the TMHF groups. There appeared to be no significant spatial memory differences that trended over time. These data are significant because they support the view that iron overload and deficiency have lasting effects on brain morphology and inflammation into adulthood. The application of this iron-loading model to assess the relationship between neurodegenerative disease processes and brain iron is currently underway.

Title: Early exposure to general anesthesia impairs the presynaptic machine for neurotransmitter release

Authors: *N. LUNARDI[1], H. P. OSURU[2], A. OKLOPCIC[3], P. DIANA[4], C. DEFREITAS[3], V. JEVTOVIC-TODOROVIC[2];
[1]Anesthesiol., Univ. of Virginia Hlth. Syst., Charlottesville, VA; [2]Anesthesiol., Univ. of Colorado, Denver, Denver, CO; [3]Univ. of Virginia, Charlottesville, VA; [4]Anesthesiol., Universita' degli Studi di Padova, Padova, Italy

Abstract: Background: The release of neurotransmitter in the synaptic cleft is a highly specialized process, achieved through the coordinated actions of numerous proteins that form the so-called pre-synaptic machine for neurotransmitter release. In recent years it has become evident that the modulation of the expression of key release machinery proteins determines essential properties of synaptic transmission at a given synapse, by affecting docking, priming and exocytosis of synaptic vesicles. Our recently published data indicate that exposure to general anesthesia (GA) in the early postnatal period may impair the release of neurotransmitter at developing excitatory synapses, as manifested by a decrease in the number of vesicles docked at the release site in the subiculum of rats five days after the initial exposure.
Hypothesis: We hypothesized that GA may have detrimental effects on the pre-synaptic machine for vesicle release. To test our hypothesis, we focused on three key components of the protein complex for synaptic release: 1) Synapsin, which is essential in spatially segregating vesicles in the reserve pool and releasing them toward the readily releasable pool upon phosphorylation 2) Complexin I, which transforms vesicles into an active "superprimed" state and 3) Synaptotagmin I, which is crucial in triggering fusion of complexin-activated vesicles upon calcium entry into the pre-synaptic terminal.
Methods: We exposed postnatal day 7 (P7) rats to a clinically relevant combination of midazolam, nitrous oxide and isoflurane at the peak of synaptogenesis, and performed western blot assays to quantify the protein level of total synapsin, phospho-synapsin, synaptotagmin I and complexin I in the subiculum of P12 rats.
Results: We found that the levels of synapsin and its active phosphorylated form, phospho-synapsin, are decreased by more than one third in GA-exposed rats compared to sham-controls

(***, P=0.0001 and 0.0008, respectively). Likewise, there was a significant decrease in the level of synaptotagmin I (***, P=0.0006) and complexin I (***, P=0.0007) in experimental rats compared to sham-controls.
Conclusion: Our data provide proof of concept that exposure to GA at the peak of brain development can impair the expression and activity level of key release machinery components, several days after the initial exposure. In view of a substantial body of knowledge indicating persistent cognitive deficits following an early exposure to GA, further studies are warranted to examine the effects of GA-induced impairment of the pre-synaptic machine for neurotransmitter release on developmental synaptic transmission, plasticity and cognitive outcomes.

Title: Inhaled anesthetic sevoflurane-induced up-regulation of pro-apoptosis proteins in infant monkey brains

Authors: ***Q. GU**, F. LIU, S. SARKAR, S. LIU, J. KANUNGO, C. WANG, W. SLIKKER, Jr., M. G. PAULE;
FDA Natl. Ctr. for Toxicological Res., Jefferson, AR

Abstract: It has been shown previously that general anesthesia during early postnatal development can cause cell death in infant animal brains. However, current knowledge remains limited with regard to the molecular mechanisms underlying this phenomenon. To further analyze pathways involved in the adverse effects of general anesthesia on the developing brain at the molecular level, the present study focuses on the expression of pro-apoptotic proteins in the frontal cortex of rhesus monkeys following exposure to sevoflurane, an inhaled anesthetic for the induction and maintenance of general anesthesia. Compared to the control animals which received room air only, exposure to a clinically relevant concentration of sevoflurane (2.5%) for 9 hours increased the level of the pro-apoptotic proteins Bcl2-associated X (BAX) (+87%), caspase 2 (+723%) and caspase 9 (+628%), suggesting enhanced apoptosis signaling. However, not all pro-apoptotic proteins examined thus far showed up-regulation. For example, Bcl-2

homologous antagonist/killer (BAK), another prominent pro-apoptotic protein, displayed undifferentiated expression levels between the control and treated brains, suggesting further that the up-regulation of pro-apoptotic proteins triggered by the sevoflurane treatment was selective. In addition, extracellular-signal-regulated kinase (ERK), an up-stream regulator of the apoptosis process, was also examined. While the total level of ERK remained unchanged, the level of phosphorylated ERK was increased by 65%, indicating enhanced activity of ERK following sevoflurane exposure. These results suggest that sevoflurane-induced cell death in the infant brain involves the over-expression or enhanced activities of a number of specific pro-apoptotic proteins, which eventually lead to cell death. Further molecular analyses of key signaling proteins may help to better understand the molecular mechanisms underlying general anesthesia-induced cell death in the developing brain.

Abstract: Neurotoxicity may occur in cancer patients and survivors during or after chemotherapy. Cognitive deficits associated with neurotoxicity can be subtle or disabling and frequently include disturbances in memory, attention, executive function and processing speed. Searching for pathways altered by anti-cancer treatments in cultured primary neurons, we discovered that doxorubicin, a commonly used anti-neoplastic drug, significantly decreased neuronal survival. The drug promoted the formation of DNA double-strand breaks in primary

neurons and reduced synaptic and neurite density. Pretreatment of neurons with levetiracetam, an FDA-approved anti-epileptic drug, enhanced survival of chemotherapy drug-treated neurons, reduced doxorubicin-induced formation of DNA double-strand breaks, and mitigated synaptic and neurite loss. Thus, levetiracetam might be part of a valuable new approach for mitigating synaptic damage and, perhaps, for treating cognitive disturbances in cancer patients and survivors.

Title: Mitochondrial complex 1 mutation causes anesthetic-induced mortality in fruit flies

Authors: *M. PEROUANSKY[1], C. LOEWEN[2], Z. OLUFS[3], B. GANETZKY[4];
[1]Dept. of Anesthesiol., Univ. of Wisconsin Madison Dept. of Anesthesiol., Madison, WI; [2]Dept. of Genet., Univ. Wisconsin Madison, Madison, WI; [3]Dept. of Anesthesiol., Univ. of Wisconsin, Madison, WI; [4]Dept. of Genet., Univ. of Wisconsin, University of Wisconsin-Madison, WI

Abstract: Objective: to test whether a loss-of-function mutation in a mitochondrial complex 1 subunit affects sensitivity to volatile general anesthetics (VGAs).
The *Drosophila* NADH dehydrogenase 23 kDa subunit (ND23) is a highly conserved, 'core' subunit of mitochondrial complex 1. Mutations in the human homolog of *ND23* (*Ndufs8*) cause Leigh's syndrome. We discovered a novel, non-synonymous point mutation in *ND23* (*$ND23^{60114}$*) that shortens lifespan and also causes progressive neurodegeneration in flies. We exposed 11-13 day-old *$ND23^{60114}$* flies for two hours to either 2% isoflurane or 3.5% sevoflurane in air and assessed mortality after 24 hrs.
Results: 1 hour after exposure to isoflurane 0.6 ± 0.6% of control flies (wild-type strain) remained immobile, compared to 14.6 ± 3.1% of *$ND23^{60114}$* mutant flies. Twenty-four hours after exposure 0.2 ± 0.2% of control flies were dead, compared to 56 ± 4.5% of mutant flies (see

Figure). Exposure to sevoflurane did not lead to an appreciably increased mortality.
Conclusions: A loss of function mutation in *ND23* renders flies exquisitely sensitive to the toxic effects of isoflurane. Increased sensitivity to the behavioral effects of VGAs has been previously observed in electron transport chain mutants in other model organisms. Humans with analogous mutations are at high risk for adverse effects when exposed to VGAs.

Title: Bortezomib induced apoptosis of adult neural stem cells and post-chemotherapy cognitive impairment in mice

Authors: *P. HUEHNCHEN[1,2,3], W. BOEHMERLE[1,2,3], M. ENDRES[1,2,3,4,5];
[1]Charite Universitaetsmedizin Berlin, Berlin, Germany; [2]Berlin Inst. of Hlth., Berlin, Germany; [3]Cluster of Excellence NeuroCure, Berlin, Germany; [4]Ctr. for Stroke Res. Berlin, Berlin, Germany; [5]German Ctr. for Neurodegenerative Dis., Berlin, Germany

Abstract: Neurotoxic phenomena are among the most common side effects of antineoplastic chemotherapy and present an unmet medical need. Changes of cognitive functions in cancer patients undergoing chemotherapy - often referred to as post-chemotherapy cognitive impairment (PCCI) or "chemobrain" - are diffuse, difficult to attribute to individual drugs and the underlying pathomechanisms are unclear. Bortezomib is a highly potent 26S proteasome inhibitor and mainly used in the treatment of multiple myeloma, but currently under clinical evaluation for the treatment of various solid tumors as well as antibody-mediated autoimmune disorders. The goal of this study is to assess cognitive and histologic changes after bortezomib therapy with a focus on adult hippocampal neurogenesis and evaluate apoptotic pathways in cultured stem and progenitor cells. We used an animal model where adult male C57Bl/6 mice are given a total of 12 intraperitoneal injections of 0.4 mg/kg bodyweight bortezomib (human equivalent dose of 1.2 mg/m^2 body surface) or vehicle over the course of four weeks. Apart from an axonal sensory polyneuropathy, which we previously characterized, the treatment in general was well tolerated. However, bortezomib-treated mice developed distinct visuo-spatial learning and memory deficits as witnessed in the Morris water maze task, while working memory and object recognition were unimpaired. Preliminary histologic analysis revealed a reduced hippocampal cell proliferation after bortezomib therapy that needs to be further characterized. In vitro, brief exposure of murine adult neural stem cells with nanomolar bortezomib concentrations led to severe cytotoxicity, whereas postmitotic mature hippocampal neurons were less susceptible. Apoptosis in neural stem and progenitor cells was mainly mediated by caspase-dependent mechanisms. We hypothesize a disturbance in intracellular calcium homeostasis as initiator of apoptosis, which we are currently further investigating.
In summary, we established a novel animal model to study bortezomib induced PCCI in mice. The preliminary results hint at a link between adult neurogenesis and cognitive dysfunctions due to bortezomib therapy with a caspase-dependent apoptotic mechanism targeting adult neural stem and progenitor cells. Further identification of molecular targets will allow the design of preventive treatment approaches to counteract neurotoxic phenomena.

Title: Effect of lead on the expression of metallothionein-3 in the brain of young rats

Authors: *A. RAHMAN[1], K. KHAN[2];
[1]Dept. of Food Sci. and Nutr., Kuwait Univ., Kuwait, Kuwait; [2]Dept. of Anat., Fac. of Medicine, Kuwait Univ., Kuwait, Kuwait

Abstract: Lead (Pb) is a known neurotoxicant which impairs learning and memory. Metallothioneins (MTs) are metal binding proteins that protect cells from heavy metal toxicity. The brain-specific MT-3 has been implicated in the etiology of neurodegeneration. The purpose of this study was to investigate whether exposure to low levels of Pb has an effect on the expression of MT-3 in the rat brain. Wistar rat pups (n=10/group) were exposed to 0.2% Pb-acetate via their dams' drinking water from PND 1 to 21 and directly via drinking water from weaning until PND 30. The control group (n=10) was given regular water. Expression of MT-3 was measured by Western blot (WB) and by immunohistochemistry in various regions of the brain. Western blot analysis of the whole brain lysate from PND21 rats showed two distinct bands; one at ~30kD and one at ~10 kD. Quantitation of these bands revealed that Pb exposure significantly increased MT-3 expression in the brain of PND21 rats. In PND30 rats, only the 30kD band was seen; the 10kD band was not observed. Similar to the PND21 rats, Pb exposure resulted in increased expression of MT-3 in the PND30 rats. From the hippocampal lysate, only the 30kD band was observed and its quantitation revealed that at both PND21 and PND30 the expression of MT-3 was significantly decreased after Pb exposure. Number of immunoreactive neurons in a standardized area of different brain regions were counted and compared between control and Pb-exposed rats. At PND21, more immunoreactive neurons were observed in the cortex and in the CA1, CA2 and CA3 regions of the hippocampus in the Pb-exposed rats compared to control. No effect was seen in the dentate gyrus and the thalamus. At PND30, MT-3 immunoreactive neurons were increased only in the cortex of Pb-exposed rats compared to control, whereas in the thalamus and the CA2 and CA3 regions of the hippocampus fewer MT-3 immunoreactive neurons were observed in the Pb-exposed rats compared to control. CA1 and dentate gurus were largely unaffected. These results suggest that the effect of Pb on MT-3 expression is dependent on the developmental stage of the rats and is brain-region specific.

Title: Abnormal visual function in a mouse model of hemochromatosis with retinal iron loading

Authors: *E. A. MILWARD[1], A. SHAHANDEH[1], D. M. JOHNSTONE[2], A. BRANDLI[3]; [1]The Univ. of Newcastle, Callaghan, Australia; [2]Univ. of Sydney, Sydney, Australia; [3]Univ. of Melbourne, Melbourne, Australia

Abstract: Iron accumulation in the retina may contribute to age-related macular degeneration (AMD) and other serious eye diseases but the mechanisms involved remain unclear. We have assessed molecular and functional changes in the retina of a mouse model of iron loading with defects in the hemochromatosis *Hfe* and transferrin receptor 2 genes on an AKR background (*Hfe*$^{-/-}$x*Tfr2*^{mut}).

We demonstrated substantial retinal iron accumulation by diaminobenzidine-enhanced Perls' stain in the retinal pigment epithelium, photoreceptors, ciliary body and other structures in 9-month-old *Hfe*$^{-/-}$x*Tfr2*^{mut} mice compared to wild-type mice. Immunofluorescence revealed changes in glial fibrillary acidic protein (GFAP), protein kinase α (PKC-α) and glutamine synthase (GS) consistent with retinal stress and degenerative changes.

Ferritin immunofluorescent labelling was increased in *Hfe*$^{-/-}$x*Tfr2*^{mut} mice compared to wild-type mice and gene expression microarrays showed overexpression of iron-related genes, including ferroportin (*Slc40a1*; fold-change 1.394, p=0.03) and transferrin (*Tf*; fold-change 1.843, p=0.002). There were significant expression changes of multiple genes linked to vision disorders including AMD, retinitis pigmentosa, cone-rod dystrophies, congenital stationary night blindness and bradyopsia (all p<0.05).

Retinal function was performed by electroretinography on dark-adapted anesthetized *Hfe*$^{-/-}$x*Tfr2*^{mut} and wildtype AKR mice (n=6/group) between 10 am and 3 pm to reduce circadian fluctuation. The electroretinogram a-wave and b-wave measure photoreceptor and bipolar cell function respectively. After normalization, there were no differences in amplitude or latency of the a-wave (p>0.05) but a reduction of 41% in b-wave amplitude (p=0.03) with 19% delay in the latency (p=0.003). The b-wave is a measure of outer nuclear bipolar cell function and reflects both photoreceptor and synaptic function in the outer plexiform layer of the retina. The changes are consistent with abnormalities involving Müller cells and bipolar cells.

These results provide strong evidence that abnormal retinal iron loading, in association with mutations in the *Hfe* and *Tfr2* genes, can lead to impaired visual function, in conjunction with cellular and molecular changes consistent with retinal stress and degeneration, and may contribute to various important eye diseases.

Title: The effect of an organophosphorus agent on human neuroblastoma cell line SK-N-SH

Authors: *Y. YAMADA[1], K. YAMADA[1], H. SHIRAISHI[2], A. NAMERA[3], Y. ARIMA[3], M. NAGAO[3];
[1]Fac. of Engineering, Kindai.Univ., Higashihiroshima-Shi, Japan; [2]Daiyukai.First Hosp. Dept. of Gynecol. and Obstet., Ichinomiya, Japan; [3]Inst. of Biomed. and Hlth. Sciences,, Hiroshima, Japan

Abstract: Organophosphates are used in insecticides and as a poison gas in warfare. As acute toxicity, organophosphates are an acetylcholinesterase inhibitor, but the mechanism of action of the chronic toxicity is unclear. Twenty years have passed since a horrifying terrorist attack with sarin gas (isopropyl methyl phosphonofluoridate) at Tokyo. There are many people that have been plagued by severe sequelae and neurological symptoms including deficits in attention and memory, depression, headache, dizziness, insomnia, numbness, ataxia, muscle fatigue, and especially paresthesia in the extremities. We synthesized a sarin-like [bis (isopropyl methyl) phosphonate, BIMP]. To elucidate the mechanism of the chronic toxicity the BIMP toxicity against the human neuroblastoma cell line SK-N-SH and differentiated SK-N-SH by retinoic acid were examined. To differentiate SK-N-SH into neuronal cells, cells were grown in MEMα including 5% FCS together with 40 μM retinoic acid, NGF and BDNF on polylysine coated plates and the medium were replaced every 3 days for 8-30 days. For estimating the toxicity of BIMP, cell viability was analyzed using the conventional MTT reduction assay after incubation for 24 hours. To evaluate the effect of BIMP on the wound healing process,the scratch assay was done using SK-N-SH and differentiated SK-N-SH cells. When the stresses such as toxicity or oxidation are applied to the cells, the endoplasmic reticulum stress causes and increases abnormal proteins. Under the presence of BIMP, the changes of endoplasmic reticulum stress response were examined. The expression level of DNA-damage-inducible transcript (CHOP), which is known as the endoplasmic reticulum stress marker gene were measured by RT-PCR. BIMP inhibited the cell proliferation of SK-N-SH and the IC_{50} value was 44 μM. BIMP showed the inhibitory effect of wound healing on SK-N-SH and differentiated SK-N-SH using a scratch

assay. Expression of major ER related factors CHOP increased after incubation of BIMP for 3 hrs. These results suggested that BIMP induced the chronic neural toxicity by the mechanism related to endoplasmic reticulum stress.

Title: Propofol affects neurodegeneration and neurogenesis by regulation of autophagy via its effects on intracellular calcium homeostasis

Authors: H. QIAO[1,2], Y. LI[3], Z. XU[4], W. LI[1], Z. FU[3], G. LIANG[2], *H. WEI[2];
[1]Dept. of Anesthesiol., The Eye Ear Nose and Throat Hosp. of Fudan Univ., Shanghai, China; [2]Dept Anethesiol & Critical Care, Univ. Pennsylvania, Philadelphia, PA; [3]Dept. of Pain Med., Provincial Hosp. Affiliated to Shandong Univ., Jinan, China; [4]First Maternity and Infant Hospital, Tongji Univ. Sch. of Med., Shanghai, China

Abstract: The effects of most widely used intravenous anesthetic propofol on neurogenesis and associated mechanisms are still not clear. In human cortical neural progenitor cells (NPCs), we investigated the effects of propofol on intracellular calcium homeostasis via activation of the ryanodine and inositol 1,4,5-trisphosphate ($InsP_3$) receptors. We also studied propofol-mediated effects on autophagy, cell survival and neurogenesis. Cell viability was measured by MTT reduction and LDH release assays. Changes on the cytosolic calcium concentration ($[Ca^{2+}]_c$) were evaluated using Fura-2 AM dye, in the presence or absence of the ryanodine receptor antagonist, dantrolene, the $InsP_3$ receptor antagonist, xestospongin C (Xc), intracellular calcium chelator, BAPTA-AM, or the $InsP_3$ production inhibitor, lithium. Autophagy activity was determined by measuring LC3II expression using Western blot. NPC proliferation and

differentiation were also evaluated by bromodeoxyuridine incorporation and immunostaining with neuronal and glial markers. Propofol dose- and time-dependently induced cell damage, most robustly at 200 μM for 24 h. This effect was inhibited by co-treatment with dantrolene, Xc, lithium, BAPTA-AM or autophagy inhibitor 3-MA, but was promoted by autophagy inducer, rapamycin, and autophagy flux inhibitor, bafilamycin. Propofol also dose- and time-dependently elevated the level of the autophagy biomarker LC3II, which was further increased in the presence of bafilomycin but inhibited by dantrolene and Xc. Propofol at 200 μM significantly increased $[Ca^{2+}]_c$, which was partially inhibited by dantrolene, xestospongin C, lithium or BAPTA-AM. Propofol at a clinically relevant concentration (10 μM) stimulated proliferation, which could be abrogated by Xc and dantrolene but proliferation was not affected by either 3-MA or rapamycin. Propofol significantly impaired proliferation at a pharmacological concentration (200 μM), which could be rescued by Xc, dantrolene, 3-MA but was potentiated by rapamycin. Propofol (10 μM) for 24 h increased neuronal differentiation but decreased glial differentiation, while 200 μM propofol for 24 h increased glial differentiation and decreased neuronal differentiation. These dual effects of propofol can be mitigated by co-treatment with either Xc or dantrolene. Propofol dose-dependently induced autophagy activity, cell damage and had dual effects of both promoting and inhibiting neurogenesis in NPCs by differential activation of $InsP_3$ or ryanodine receptor calcium channels. Propofol mediated cell survival or growth is closely associated with its effects on autophagy.

Title: Aspartame causes dose dependent hippocampal injury in adult male mice

Authors: ***P. U. NWOHA**[1], A. Y. ONAOLAPO[2];
[1]Obafemi Awolowo Univ., Ile-Ife, Nigeria; [2]Anat., Ladoke Akintola Univ. of Technol., Ogbomoso, Nigeria

Abstract: Aspartame is a widely consumed artificial food sweetener. But opinions differ on its possible adverse neurological effects following consumption. This study therefore investigated the effects of oral administration of aspartame on the histomorphology of the hippocampus in mice. Sixty adult male mice weighing 20 to 22 g, obtained from Animal Holding of Obafemi

Awolowo University were used. Animals received vehicle (distilled water) or one of four doses of aspartame (20, 40, 80 and 160 mg/kg) daily for 28 days via an oral cannula. Animals were properly taken care of, according to accepted ethics and guidelines. At the end of the experiment, the animals were sacrificed and sections of hippocampus processed, and stained with H & E, and cresyl violet, and measured. Data obtained were expressed as mean ± S.E.M and analysed using one-way ANOVA followed by Tukey HSD test. Results showed increased loss of pyramidal and granule neurons, increased glial cells proliferation, and presence of dark staining neurons, with increased dosing. Morphometry revealed significant increase in total cell count and glial cell density, and decrease in cell size and pyramidal cell density at all doses. Granule cell density increased at 20 and 40 mg/kg, and decreased at 80 and 160 mg/kg aspartame consumption. The study concluded that oral administration of aspartame produced dose-dependent hippocampal damage.

Title: The effects of silica nanoparticles on affective and cognitive behaviors, and on synapse *In vivo* and *In vitro*

Authors: *R. YOU[1], S. S. Y. CHENG[1], C. H. L. HUNG[1,2], Y. S. HO[3], R. C. C. CHANG[1,4,5]; [1]Lab. of Neurodeg. Dis., Sch. Biomed. Sci., HKU, Hong Kong SAR, China; [2]Inst. of Chinese Med. Ctr. of Heart, Brain, Hormone and Healthy Aging, LKS Fac. of Medicine, HKU, Hong Kong SAR, China; [5]State Key Lab. of Brain and Cognitive Sciences, HKU, Hong Kong SAR, China

Abstract: Backgrounds Silica nanoparticles (SiO_2-NPs) are typical and major components of mineral dust and many other airborne pollutants in the ambient air. Accumulating evidence show that exposure to SiO_2-NPs may induce neurotoxicity *in vitro* and neuroinflammation. Both of

which are involved in the pathogenesis of neurodegenerative diseases and/or mood dysfunction. However, the effect of SiO_2-NPs on affection and cognition is not known. Moreover, most of the current studies focus on the effects of SiO_2-NPs on neuroinflammation and its contribution to neurotoxicity. The direct effect of SiO_2-NPs on neuron, especially synapse, is poorly known. In the current study, we employed fluorescein isothiocyanate-tagged SiO_2-NPs (FITC-SiO_2-NPs) to investigate the effects of SiO_2-NPs on affection and cognition in mice, and on synapse both *in vivo* and *in vitro*. **Methods** We consecutively exposed 3-month-old male C57BL/6N mice to either vehicle (sterile PBS) or FITC-SiO_2-NPs suspension through intranasal instillation, and subjected the mice to a battery of behavior tests after 1 month and 2 months treatment. We used open field test for locomotor function, elevated plus maze test for anxiety, social interaction test for social activity, accelerated rotarod test for motor function, and novel object recognition (NOR) test and Morris water maze (MWM) test for cognition. Synaptosome fractions were extracted from frontal cortex and hippocampus using Syn-PER reagent. Western-blotting analysis was used to study the protein levels of synaptic proteins in the synaptosomes. FM 1-43 dye was used to study the endocytosis and exocytosis of the synaptosome. In the *in vitro* study, we treated 14-day primary culture of cortical neurons with FITC-SiO_2-NPs for 48 h, and examined the protein levels of synaptic proteins via immunocytochemical analysis and the function of synapse via FM 4-64 FX dye. **Results** We found that FITC-SiO_2-NPs did not affect the locomotor and motor function in mice. However, it decreased social activity after 1-month treatment. 2-month treatment induced anxiety, and impaired short-term memory in NOR test and spatial learning in MWM test. Meanwhile, we found a decrease of synapsin I and an increase of synaptophysin both *in vivo* and *in vitro*. We also found that the exocytosis of frontal cortex synaptosome and cell culture of primary cortical neurons were impaired. **Conclusion** Exposure to FITC-SiO_2-NPs results in mood dysfunction and cognitive impairment in mice, and it may attribute to the structural and functional changes in synapse.

Title: The effect of arsenic exposure on behavior in rats of various age groups and on pups development

Authors: *T. BIKASHVILI[1], T. LORDKIPANIDZE[2], N. GOGICHAISHVILI[2], N. POCHKHIDZE[2];
[1]I.Beritashvili Ctr. of Exptl. Biomedicine, Tbilisi, Georgia; [2]Ilia State Univ., Tbilisi, Georgia

Abstract: Arsenic toxicity is a worldwide health concern as several millions of people are exposed to this toxicant via drinking water, and exposure affects almost every organ system in the body including the brain. Exposure to arsenic induces behavioral and cognitive deficits in both human populations and in rodent models. The effect of arsenic exposure on rat behavior was studied in two different age groups (young and adult). Animals in control groups were given regular water, while the rats from the experimental groups drank the water with final arsenic concentration of 68 mg/L, for three months. Offspring of rats given this dose of arsenic before pregnancy, during pregnancy, and for one month after parturition also were studied. All control and experimental groups were tested: in open field and in elevated plus maze to study the exploratory and anxiety-related behavior; in novel object recognition test to examine the efficacy of memory enhancing compounds; in multi-branched maze to estimate the learning process. The body weight gain abnormalities were observed in all experimental groups. After three months of arsenic exposure the average body weight in young and adult groups and 30-day-old pup's (offspring of arsenic exposure parents) lags behind 20%, 6% and 18%, respectively, in comparison with control animals. The data obtained in this study indicate that arsenic stimulates changes in motor and oriental-searching activity (assessed by the decreased number of lines crossed, rearing and hole reflexes) in the open field test. However, in the experimental groups (especially in the offspring), the animals demonstrated increased levels of anxiety, reflected in the decreased in open arm activity (duration and entries) of elevated plus maze, time spent in the inner circle, inner circle frequency defined by the number of visits into the inner circle of the open field, in increased duration of grooming. Object novelty discrimination index in young and adult control groups, also habituation to the environment (habituation score) in young group was higher in comparison to experimental groups (differences being statistically significant $p<0.05$). Rats from the experimental groups demonstrated impaired cognitive learning: they made more errors and need more time compared to control animals. The difficulty in learning ability was statistically significant ($p<0.05$) in pups, offspring of rats exposed to arsenic. The results suggest that arsenic exposure causes possible health problem not only for parents, but also for the fetus and results in developmental deficits. Acknowledgment. This work was supported by grant from Shota Rustaveli National Science Foundation.

Title: β-N-Methylamino-L-alanine interferes with metabolic pathways related to neurotransmission in human SH-SY5Y neuroblastoma cells as determined by metabolic profiling

Authors: *L. ERSSON[1], M. K. R. ENGSKOG[2], J. HAGLÖF[2], T. ARVIDSSON[2,4], C. PETTERSSON[2], E. BRITTEBO[3];
[2]Div. of Analytical Pharmaceut. Chem., [3]Dept. of Pharmaceut. Sci., [1]Uppsala Univ., Uppsala, Sweden; [4]Med. Product Agency, Uppsala, Sweden

Abstract: β-Methylamino-L-alanine (BMAA) is a non-proteinogenic amino acid produced by ubiquitous organisms such as cyanobacteria, diatoms and dinoflagellates. It is a developmental neurotoxin that induces long-term cognitive deficits as well as an increased ubiquitination, neurodegeneration, astrogliosis, and intracellular fibril formation in the hippocampus of adult rodents following neonatal exposure, whereas it has a low neurotoxic potency in adults rats exposed to BMAA. Recent studies by Cox and coworkers have demonstrated that long-term oral exposure of vervet monkeys to BMAA triggers neurofibrillary tangles formation and amyloid deposits in the brain whereas there were no cognitive changes.
The aim of the present study was to investigate early metabolic effects not related to excitotoxicity of BMAA in differentiated human SH-SY5Y neuroblastoma cells utilizing an analytical platform profiling approach. The cells were exposed to up to 1 mM BMAA during 24 hours and then harvested and snap-frozen prior analysis. Using HILIC-MS and NMR spectroscopy, a plentitude of significantly altered intracellular polar metabolites was detected. Metabolic profiling and multivariate pattern recognition analysis revealed significant perturbations in protein biosynthesis, amino acid metabolism and TCA-cycle. The alterations were preferentially observed in the alanine, aspartate and glutamate metabolism pathways demonstrating that BMAA can interfere with fundamental metabolic pathways related to neurotransmission. In addition, there was a significant enrichment of GABA.
The observed perturbations in amino acid/neurotransmitter metabolism pathways were not related to excitotoxicity or oxidative stress but may be of importance for synaptic plasticity, which in turn could play a role in the neurodegenerative changes induced by BMAA.

Title: Depressive-like behavior in adult rats chronically exposed to a glyphosate-based herbicide: involvement of glutamatergic excitotoxicity and oxidative stress

Authors: *D. CATTANI[1], P. A. DE OLIVEIRA[2], R. D. S. PREDIGER[2], E. B. PARISOTTO[1], D. WILHELM FILHO[1], A. Z. PACHECO DE SOUZA[1];
[1]Dept. of Biochem., [2]Dept. of Pharmacol., Federal Univ. of Santa Catarina, Florianópolis, Brazil

Abstract: Epidemiological studies have demonstrated that exposure to pesticides is associated to an increased risk of neurological disorders such as depression and neurodegenerative diseases. Glyphosate [N-(phosphonomethyl)glycine] formulations are the most widely used herbicides worldwide. This study investigated the effects of chronic oral exposure to glyphosate-based herbicide (GBH) on depressive-like and/or anhedonia-like behavior and in the hippocampus of adult male Wistar rats. Female rats were exposed to 1% GBH in drinking water (0.36% or ~ 21.3 mM glyphosate) from gestational day 5 until the offspring was 60 days old. The forced swimming test was used as a model of depressive-like behavior; the locomotor activity was investigated through open field and rotarod tests and sucrose consumption was used as anhedonia-like behavior. For biochemical analysis, hippocampal homogenates were used to evaluate the $^{45}Ca^{2+}$ influx; L-[^{14}C]-glutamate uptake and oxidative stress markers. A depressive-like behavior was observed in GBH-treated rats as demonstrated by the prolonged immobility time during forced swimming test. Moreover, there were no effects on anhedonia-like behavior or locomotor activity in the GBH-treated animals. The ex vivo studies showed a decreased L-[^{14}C]-glutamate uptake and increased $^{45}Ca^{2+}$ influx in hippocampal slices of GBH-treated 60-day old rats, suggesting the induction of glutamatergic excitotoxicity in hippocampus. There was also an increased activity of catalase and glutathione S-transferase indicating a defense reaction against oxidative damage. Taken together, the results demonstrated that chronic exposure to GBH during the development and later on might lead to glutamate excitotoxicity and oxidative

stress in the hippocampus of adult rats. These neurochemical events may contribute, at least in part, to the depressive-like behavior observed in the GBH-treated rats.

Title: Assessing drug neurotoxicity and functional mode of action using high-throughput MEA recording from human iPSC neurons combined with multivariate spike train analysis

Authors: *K. JÜGELT, A. STEDER, O. H. U. SCHROEDER, B. M. BADER;
NeuroProof GmbH, Rostock, Germany

Abstract: Identification of neurotoxic effects in drug discovery leads to significant attrition rates, and the lack of suitable in vitro test systems to identify sub-cytotoxic concentrations partly accounts for this. Additionally, the low throughput and high animal costs for presently used brain slice or behavior assays for predicting seizure risk is increasing costs, which is accompanied by the fact that results from rodent tests not always translate into the human situation.
Human stem cell (hiPSC)-based in vitro platforms promise to serve as an alternative to animal in vivo or in situ models. Testing new lead compounds in hiPSC-derived functional neuronal in vitro systems will be physiologically more relevant and further improve current state-of-art by offering higher throughput and higher content. We cultured commercially available hiPSC neurons on multiwell microelectrode arrays which are designed for high-throughput screening. After several weeks in vitro, we tested known neurotoxins such as seizurogenic compounds an analyzed the recorded spike trains by our in-house software NPwaveX computing hundreds of parameters to describe the phenotypic effects in four well-established categories (general activity, synchronicity, burst structure, regularity). The established fingerprints reveal toxin- and MOA-specific parameter panels identified by multivariate classification analysis. We compare the results between human iPSC-derived neuronal networks and those from functionally mature primary mouse cortical networks.
In summary, our data show that the MEA technology allows dissecting the functional differences between hiPSC- and mouse neuronal culture model when treated with known neurotoxins and therefore provides a tool for investigating and comparing the safety margin of novel drug

candidates between rodent and human cell background and thereby complements the prediction of functional-neurotoxic and seizurogenic risk assessment.

Title: A rat model of nerve agent exposure applicable to the pediatric population: The anticonvulsant efficacies of atropine and GluK1 antagonists

Authors: *J. P. APLAND[1], S. L. MILLER[2], V. ARONIADOU-ANDERJASKA[3], T. H. FIGUEIREDO[2], E. M. PRAGER[4], C. P. ALMEIDA-SUHETT[4], M. F. M. BRAGA[3]; [1]Neurobehavioral Toxicol, USAMRICD, Gunpowder, MD; [2]Dept. of Psychiatry, [3]Dept. of Anatomy, Physiology, and Genetics, and Dept. of Psychiatry, [4]Dept. of Anatomy, Physiology, and Genet., USUHS, Bethesda, MD

Abstract: Inhibition of acetylcholinesterase (AChE) after nerve agent exposure induces status epilepticus (SE), which causes brain damage or death. The development of countermeasures appropriate for the pediatric population requires testing of anticonvulsant treatments in immature animals. In the present study, exposure of 21-day-old (P21) rats to different doses of soman, followed by probit analysis, produced an LD50 of 62 μg/kg. The onset of behaviorally observed SE was accompanied by a dramatic decrease in brain AChE activity; rats who did not develop SE had significantly less reduction of AChE activity in the basolateral amygdala than did rats who developed SE. Atropine sulfate (ATS) at 2 mg/kg, administered 20 min after soman exposure (1.2×LD50), terminated seizures. ATS at 0.5 mg/kg, given along with an oxime within 1 min after exposure, allowed testing of anticonvulsants at delayed time-points. The AMPA/GluK1 receptor antagonist LY293558 or the specific GluK1 antagonist UBP302, administered 1 h post-exposure, terminated SE. There were no degenerating neurons in soman-

exposed P21 rats, but both the amygdala and the hippocampus were smaller than in control rats at 30 and 90 days post-exposure; this pathology was not present in rats treated with LY293558. Behavioral deficits present at 30 days post-exposure were also prevented by LY293558 treatment. Thus, in immature animals, a single injection of atropine is sufficient to halt nerve agent-induced seizures, if administered timely. Testing anticonvulsants at delayed time-points requires early administration of ATS at a low dose, sufficient to counteract only peripheral toxicity. LY293558, administered 1 h post-exposure, prevents brain pathology and behavioral deficits.

Title: Pupillary light response in guinea pigs and swine exposed to organophosphate agents

Authors: E. D. CLARKSON[1], *M. C. MOFFETT[1], J. E. MORGAN[1], K. H. SMITH[1], S. M. SCHULZ[1], J. K. CHANDLER[1], C. L. ROUSAYNE[1], C. KOLANKO[2];
[1]USAMRICD, Aberdeen Proving Ground, MD; [2]Eyemarker Systems, Inc., Morgantown, WV

Abstract: Here we report a study to define and quantify the relationship between organophosphate agent exposure with acetylcholinesterase (AChE) inhibition and the ocular biomarkers that are induced. A guinea pig model was exposed to varying concentrations of parathion (pesticide), soman, and VX (nerve agents) to methodically detail both the temporal and quantitative occurrence of pupillary deficits (anticholinesterase biomarkers) to determine the most sensitive, accurate diagnostic algorithms in these animal models. Dose-response curves and temporal-response curves for both pupillary deficits and generalized symptoms were developed for each agent used. Based upon previous studies, dose ranges were chosen to incorporate lethal and sub-lethal exposures without decreasing the potential sensitivity of the ocular biomarkers. In addition, AChE assays were performed at various time points post-exposure over 24 hours. The key finding of this study was that, after exposure to organophosphates, changes in pupillary response were detected prior to changes in AChE levels in guinea pigs. We have conducted limited testing in swine in which VX at 1.7 LD_{50} (n=3) or 0.7 LD_{50} (n=3) was placed on a

swine's neck, and the animal was monitored over 6 hours. For the higher-dose animals, measurable AChE inhibition and pupillary response occurred at 1 hour and for the lower dose at 3 hours. The percent change in pupillary response was greater than the percent AChE inhibition. This opens the possibility of early detection of organophosphate exposure in a non-invasive manner that does not require the use of enzyme markers.

Title: Investigation of the resistance to glutamate-induced excitoxicity in mouse motor neuron-like NSC-34 cells on graphene oxide films

Authors: ***G. SENGUL**[1], S. TASDEMIR[2], P. CORUK[3], B. KAYHAN[3], A. SENDEMIR URKMEZ[4];
[1]Ege Univ. Sch. Med., Izmir, Turkey; [2]Bioengineering, Ege University, Fac. of Engin., Izmir, Turkey; [3]Neurosci., Ege University, Inst. of Hlth. Sci., Izmir, Turkey; [4]Ege University, Fac. of Engin. and Ege University, Grad. Sch. of Natural and Applied Sci., Izmir, Turkey

Abstract: Excess glutamate release leads to glutamate-induced excitotoxicity and neuronal death by overstimulating NMDA-type glutamate receptors. Graphene, a monolayer of sp2-bonded carbon atoms, is a quasi-two-dimensional (2D) material with unique electrical and chemical properties, enabling electrical activity of the cells and facilitating the integration with neural

tissues. The aim of this *in vitro* study was to investigate the behavior of motor neurons on graphene oxide (an oxidized form of graphene) substrates and under glutamate-induced excitotoxicity which has been shown to be an important factor in many neurodegenerative diseases. For this purpose, we used graphene oxide film as a substrate for motor neuron-like NSC34 cells, a hybrid cell line produced by fusion of mouse neuroblastoma with mouse motor neuron-enriched primary spinal cord cells. NSC-34 cells were grown in DMEM high glucose formulation containing 10% fetal bovine serum. Cells were seeded on GO films and cells cultivated on tissue culture polystyrene were used as control. DMEM-F12 with reduced serum concentration (1%) and 1% non-essential amino acids as used for differentiation. After 6 days of differentiation, L-glutamic acid induced excitotoxicity was applied on NSC-34 cells on both surfaces. Following stress, morphologies of cultured neurons were examined by scanning electron microscopy (SEM) and immunostaining. Cell viability was measured by MTT assay. SEM results showed that the cells were attached on GO films. Cell viability (MTT) and toxicity (LDH) assays suggested a resistance to glutamate-induced excitoxicity in NSC-34 cells on graphene oxide films.

Title: Inhibition of necroptosis by treatment with necrostatin-1 or RIP1 siRNA potentiates taxol-induced neuronal death via the activation of ERKs in mouse cortical cultures

Authors: *J.-K. KIM, S. HWANG;
Chonnam Nat'l Univ. Med. Sch., Gwangju, Korea, Republic of

Abstract: Taxol is a well-known microtubule-stabilizing anticancer drug. We have previously reported that taxol induces oxidative neuronal apoptosis by enhancing the activity of NADPH oxidase in cultured cortical cells. Present study was performed to investigate whether necroptosis and autophagic cell death pathways may participate in the taxol-induced neuronal death (TIND). We examined the effects of some selective inhibitors of apoptosis, necroptosis and autophagy on the TIND in mouse cortical cultures. Twenty-four hour exposure to 300 nM taxol induced 40 - 60% neuronal death. The TIND was significantly attenuated not only by pretreatment with anti-apoptotic agents such as Z-VAD-FMK and Z-IETD-FMK but also by pretreatment with

autophagy inhibitors such as 3-methyadenine and bafilomycin A1. Unexpectedly, pretreatment with necrostatin-1 (Nec-1, 100 μM), a selective necroptosis inhibitor, significantly potentiated the TIND. Furthermore suppression of receptor-interacting protein 1 kinase (RIP1) using siRNA also potentiated the TIND. On the other hand, the TIND was significantly attenuated by pretreatment with SP600125, a c-Jun N-terminal Kinase inhibitor but not by PD098059, a mitogen activated and extracellular regulated kinase kinase 1 inhibitor or SB203580, a p38 MAPK inhibitor. However, the enhanced neuronal death by Nec-1 or RIP1 suppression was reversed by pretreatment with PD98059 as well as SP600125, not by SB203580. These findings demonstrate that treatment with Nec-1 or suppression of RIP1 expression may enhance TIND through the activation of ERKs and suggest that RIP1 inhibition may potentiate neuronal death in mouse cortical cultures.

Title: Sex differences in oxaliplatin induced neuropathic pain behaviors

Authors: *L.-H. CHEN[1], M.-R. SHEN[2];
[1]Dept. of Pharmacol., [2]Obstetrics and Gynecology, Natl. Cheng Kung Univ., Tainan, Taiwan

Abstract: Current evidence suggests females show greater sensitivity and responses than males to chemotherapeutic drugs, including cisplatin and paclitaxel. However, sex differences in pain responses to oxaliplatin treatment still remain unclear. The aim of this study was to investigate the sex differences in mouse model of oxaliplatin-induced neuropathic pain. Mice were intraperitoneally injected with 7-mg/kg oxaliplatin on four alternate days or two cycles of 3-mg/kg oxaliplatin for 5 consecutive days, followed by 5 days of rest. In the mouse behavioral tests, oxaliplatin-induced cold allodynia was more robust in female mice; while no differences were observed between the two genders in oxaliplatin induced mechanical allodynia. Both female and male mice exhibited less locomotor activity following oxaliplatin injections. Electron

micrographs of sciatic nerves revealed that oxaliplatin caused small myelinated and non-myelinated fibers damages in both gender, large myelinated fiber damages by oxaliplatin were observed only in females. Taken together, our results suggest that females showed greater pain sensitivity and exhibited severe axonal damage in large myelinated axons of sciatic nerves after oxaliplatin treatments. In future studies, sex differences in pain responses to chemotherapeutic agents should be considered.

Title: The neurocognitive effects of vanadium in young male rats

Authors: *M. F. DE BUTTE;
Psychology, Sociology, and social work, West Texas A&M Univ., Canyon, TX

Abstract: Environmental exposure to heavy metals is a public health hazard that has been linked to cognitive and neurological deficits. Exposure to heavy metals can occur through contaminated food, water, air, or in industrial work settings. Of increasing interest in recent years are the health risks and/or benefits of exposure to the transition metal vanadium. Previous research on vanadium has shown evidence of toxicity when animals and humans are exposed including respiratory and gastrointestinal problems. Paradoxically, administration of vanadium salts has been found to ameliorate glucose tolerance as well as lower blood glucose levels in diabetic rodents as well as human patients. To date, the cognitive consequences of vanadium exposure are not well elucidated. Most studies on the effects of vanadium exposure on neurocognition examined its effects following moderate to large exposure. Hence, the purpose of the current study was to investigate whether chronic ingestion of a low dose of vanadium (.05mg/1000mg of food mash) would affect Open Field, Object Recognition, and Morris Water Maze performance in young male rats. Rats did not exhibit any signs of toxicity following the chronic ingestion of vanadium. Intriguingly, vanadium exposure improved spatial memory on day 2 of the Morris Water maze task. All rats exhibited normal locomotion and exploration when tested in the Open Field task. Vanadium exposure did not affect visual memory. This study indicates vanadium may have a positive impact on spatial memory warranting further research to better understand the potential benefits and consequences of this transition metal.

Title: Impact of aflatoxin B1 on hypothalamic neuropeptides regulating feeding behavior

Authors: ***F. TREBAK**[1,2], A. ALAOUI[2], D. ALEXANDRE[1], S. ELOUEZZANI[2], Y. ANOUAR[1], N. CHARTREL[1], R. MAGOUL[2];
[1]Neuroendocrinology, DC2N Inserm U982 Rouen Univ., Rouen, France; [2]Neuroendocrinology, Lab. of Neuroendocrinology & Nutritional and climatic Environment, Univ. Sidi Mohamed Ben Abdellah, Fac. of Sci. DM, Fes, Morocco

Abstract: The presence of mycotoxins in food is a major problem of public health as they produce immunosuppressive, hepatotoxic and neurotoxic effects. Mycotoxins also induce mutagenic and carcinogenic effects after long exposure. Among mycotoxins that contaminate food are aflatoxins (AF) such as AFB1, which is the most powerful natural carcinogen. The AF poisoning results in symptoms of depression, anorexia, diarrhea, jaundice or anemia that can lead to death, but very few studies have explored the impact of AF on neuroendocrine regulations. To better understand the neurotoxic effects of AF related to anorexia, we explored in rat the impact of AFB1 on the major hypothalamic neuropeptides regulating feeding behavior, either orexigenic (NPY, Orexin, AgRP, MCH) or anorexigenic (α-MSH, CART, TRH). We also studied the effect of AFB1 on a novel neuropeptide, the secretogranin II (SgII)-derived peptide EM66, which has recently been linked to the control of food intake. For this, adult male rats were orally treated twice a week for 5 weeks with a low dose (150µg/kg) or a high dose (300µg/kg) of AFB1 dissolved in corn oil. Repeated exposure to AFB1 resulted in reduced body weight gain, which was highly significant for the high dose of AF. Immunocytochemical and quantitative PCR experiments revealed a dose-related decrease in the expression of all the hypothalamic neuropeptides studied in response to AFB1. Such orexigenic and anorexigenic alterations may

underlie appetite disorders as they are correlated to a dose-dependent decrease in body weight gain of treated rats as compared to controls. We also found a decrease in the number of EM66-containing neurons in the arcuate nucleus of AFB1-treated animals, which was associated with a lower expression of its precursor SgII. These findings show for the first time that repeated consumption of AFB1 disrupts the hypothalamic regulation of neuropeptides involved in feeding behavior, which may contribute to the lower body weight gain associated to AF exposure.

Title: Parkin dependent mitophagy rescues retinal ganglion cell from ethambutol induced apoptosis

Authors: ***B. LEE**[1], H. JUN[2], J. KIM[2], J. KIM[1];
[1]Dept. of Biomed. Sci., Seoul Natl. Univ., Seoul, Korea, Republic of; [2]Ophthalmology, Seoul Natl. Univ. Hosp., Seoul, Korea, Republic of

Abstract: Ethambutol, one of the major component of combination pharmacotherapy regimen for drug resistance tuberculosis, is the most common causative agent of toxic optic neuropathy. Ethambutol have selective toxicity to retinal ganglion cell, but the mechanism of retinal ganglion cell death is obscure and there is no appropriate therapeutic measure for ethambutol induced toxic optic neuropathy. We found that ethambutol simultaneously induces caspase dependent apoptotic cell death and increment of autophagy flux in the retinal neuron both *in vivo* and *in vitro*. Ethambutol treatment resulted in a depolarization of mitochondrial membrane potential ($\Delta\Psi m$), transcriptional up-regulation of PINK1, PARK2, nuclear translocation of parkin, and phosphorylation of parkin at S65 in retinal neuronal cell. Ethambutol induced depolarization of $\Delta\Psi m$ and subsequent apoptosis of retinal neuron is exaggerated by si-RNA mediated *PARK2* knock-down. Co-treatment with rapamycin, an autophagy inducer, ameliorates the ethambutol induced depolarization of $\Delta\Psi m$ and caspase dependent apoptosis in retinal neuron, *in vitro.* Activation of mitophagy was evident in the retinal tissue of ethambutol induced toxic optic neuropathy mouse model and intravitreally delivered rapamycin significantly alleviated apoptosis of retinal ganglion cell. Collectively, mitophagy is a key neuroprotective mechanism in

ethmabutol induced toxic optic neuropathy and rapamycin facilitates this process in retinal neuron to protect retinal neuron from EMB induced apoptosis.

Title: Additive deficits on egocentric and allocentric learning induced after developmental manganese overexposure combined with 6-hydroxydopamine striatal lesions

Authors: ***R. A. BAILEY**[1,2], A. GUTIERREZ[1,2], J. R. HUFGARD[1], T. L. KYSER[3,2], A. M. HEMMERLE[3,2], K. B. SEROOGY[3,2], C. V. VORHEES[1,2], M. T. WILLIAMS[1,2];
[1]Neurol., Cincinnati Children's Hosp. Med. Ctr., Cincinnati, OH; [2]Neurosci. Grad. Program, Univ. of Cincinnati, Cincinnati, OH; [3]Neurol., Univ. of Cincinnati Col. of Med., Cincinnati, OH

Abstract: With neurodegenerative disorders on the rise, it has been hypothesized that environmental risk factors may play some role. Extreme manganese (Mn) overexposure (MnOE) can cause manganism, a disorder similar to, yet distinct from, Parkinson's disease (PD). Less extreme MnOE from air and water pollution is known to cause subtler effects, including being correlated with increased risk for PD. During early development, MnOE also poses risks, but whether this type of exposure predisposes individuals to Parkinsonism is unclear. To investigate this relationship, we gavaged Sprague-Dawley rats with MnCl (100 mg/kg, as a free metal) or NaCl vehicle from postnatal day (P)4 to P28 every other day. This dosing paradigm elevates blood Mn to levels similar to human exposure in areas where Mn pollution is prevalent. As adults, the animals were injected with 6-hydroxydopamine (6-OHDA) or 2% ascorbic acid into the neostriatum at a dose that does not induce motor effects. After recovery, the animals were assessed in an open-field and for egocentric learning in the Cincinnati water maze (CWM), allocentric learning in Morris water maze (MWM), and fear conditioning. After testing, the substantia nigra was examined for TH expression. Animals with MnOE or 6-OHDA alone showed deficits in egocentric and allocentric learning. These effects were increased in the group that received both exposures. MnOE had a larger effect on allocentric learning than 6-OHDA, while the effect of MnOE or 6-OHDA on egocentric learning was similar. In the open-field, MnOE animals had decreased mobility while 6-OHDA animals showed increased mobility.

Conditioned fear was not affected by MnOE or 6-OHDA. From initial cell counts, TH expression in the substantia nigra is lower in all experimental groups compared with the saline/sham controls. In conclusion, developmental MnOE may be a risk factor for Parkinsonism later in life. (Supported by NIH T32 ES07051).

Title: Effects of testosterone on cell death and cognitive deficits following postnatal exposure to isoflurane

Authors: *J. SASAKI RUSSELL, J. LEONG, M. ROTMAN, J. CHAN, J. SALL;
Anesthesia and Perioperative Care, Univ. of California, San Francisco, San Francisco, CA

Abstract: Exposure to general anesthesia during early development induces neuronal death and cognitive deficits later in life in animal models. Recent studies suggest that males are more negatively impacted by anesthesia than females, however the mechanism underlying this difference is unknown. To investigate whether the presence of testosterone in the postnatal brain during anesthesia exposure leads to or aggravates the resulting cognitive deficits, male Sprague Dawley rats underwent gonadectomy at postnatal day 2 (P2) followed by exposure to 6 hours of clinically relevant concentrations of volatile anesthetic isoflurane at P7. Non-gonadectomized littermate control groups were simultaneously exposed to either isoflurane or room air. All pups were separated from dams for the same length of time. Rats were weaned at P21 and subjected to a series of object recognition and association tasks beginning at P37. All groups performed similarly well on the Novel Object Recognition task, however the isoflurane-alone group exhibited a decreased performance in some of the more complex object recognition tasks, as seen in previous studies. This deficit was ameliorated in the isoflurane-exposed gonadectomized group. Next, we examined whether the extent of isoflurane-induced cell death that is consistently observed immediately after exposure was altered in gonadectomized rats. In a separate cohort of gonadectomized and control rats, cell death in the thalamus and hippocampus was assessed 12

hours following the anesthetic or air exposure. Cell death was similar between both isoflurane-exposed groups, regardless of gonadectomy, and was significantly higher in both groups when compared to the air-exposed group. Our results indicate that the absence of testosterone does not block cell death after anesthesia in specific brain regions of interest, however does provide some level of neuroprotection, as evidenced by the cognitive tests during adulthood. These findings suggest that the presence of testosterone during anesthetic exposure may be mechanistically involved in anesthesia-induced injury in the developing brain on a synaptic or circuit level.

Title: Resting State fMRI of Gulf War Illness patients reveals abnormal connectivity within and between different brain function networks consistent with the multi-symptom illness

Authors: *K. GOPINATH[1], V. KRISHNAMURTHY[1], L. KRISHNAMURTHY[2], B. THAPA-CHETRY[2], L. OUYANG[2], A. GOYAL[2], P. GANDHI[2], Y. FANG[2], R. BRIGGS[3], R. HALEY[2]; [1]Radiology & Imaging Sci., Emory Univ., Atlanta, GA; [2]Univ. of Texas Southwestern Med. Ctr., Dallas, TX; [3]Univ. of Florida, Gainesville, FL

Abstract: Up to 250,000 veterans of the 1991 Gulf War suffer from illness (GWI) characterized by multiple deficits in cognitive, emotion, somatosensory and pain domains. In this study we employed resting state fMRI (rsFMRI) to map impairments in brain function in GWI with advanced network analysis. 22 veterans with GWI (mean age 49.4 yrs.) and 30 normal controls (NC) (mean age 49.8 yrs.), were scanned in a Siemens 3T MRI scanner using a 12-channel Rx head coil. Written informed consent was obtained from all participants in the protocol approved by the local Institutional Review Board. rsFMRI data were acquired with a 10-min whole-brain gradient echo EPI (TR/TE/FA = 2000/24ms/90°, resolution = 3mm x 3mm x 3.5mm). The preprocessed rsFMRI data for each subject was parcellated using the AAL ROI atlas to construct a 116 node graph. The distance matrix of the graph was formed by the z-transformed cross-correlation coefficients between all nodes' ROI-averaged grey matter voxel time-series. Network based statistics (NBS) was then employed to yield significant (5000 permutations based multiple comparisons corrected $p < 0.05$) connected networks of edges which exhibit abnormally decreased or increased rsFC in GWI patients. NBS yielded one *significant* connected network

comprised of 114 AAL nodes and 404 edges which exhibited abnormally increased rsFC in GWI compared to NC (GWS > NC); and another *significant* network with 102 nodes and 228 edges which exhibited decreased rsFC in GWI (GWS < NC). The large extant of these networks indicate brain-wide impairments consistent with the multi-symptom nature of GWI. In order to further probe the brain regions which exhibited most impaired/abnormal rsFC in GWI within these two networks, binary distance matrix sub-graphs were formed for each NBS network (GWS > NC and GWS < NC) by thresholding the corresponding t-statistic matrix at 9 different p-values in the range 0.025-0.0005. The mean of the 9 degree centrality (DC) datasets was employed to assess the nodes with most impaired/abnormal rsFC in GWI. Examination of the nodes with highest DC and their associated networks revealed that GWI patients exhibit significantly ***reduced rsFC*** in sensorimotor networks and basal ganglia thalamocortical networks involved in cognition and regulation of emotion, consistent with deficits in cognitive and sensory domains seen in GWI. On the other hand GWI patients exhibit abnormally ***increased rsFC*** between somatosensory network and areas in limbic, salience and pain processing networks consistent with central pain and sensory hypersensitivity seen in GWI. Thus a strong correspondence is observed between rsFC network impairments and brain function deficits in GWI.

Title: Neurodevelopmental effects of organophosphate pesticide exposure

Authors: *E. A. FRADINGER, B. AHN, G. X. GARCIA, H. R. SCHMIDT, H. GARCIA, O. MAC, D. B. BOURGAIZE;
Biol. Dept., Whittier Col., Whittier, CA

Abstract: Organophosphate pesticides irreversibly and semi-permanently inhibit acetylcholinesterase causing an accumulation of acetylcholine at the synapse and hyperstimulation of the cholinergic neurons in the CNS and PNS. This study seeks to understand the acute effects of organophosphate pesticide exposure on developing neurons both *in vivo* and *in vitro*. Using the zebrafish model system we have shown that developmental organophosphate exposure inhibits acetylcholinesterase activity and causes changes to acetylcholine-dependent physiological processes including an increase in spontaneous movement generation at 24 hours post-fertilization and bradycardia at 48 hours post-fertilization. To further investigate the effects of these pesticides on neuronal development we have utilized the cholinergic PC-12 cell line. Differentiating PC-12 cells were shown to be sensitive to organophosphate exposure at mid to late stages of differentiation when the neurons were beginning to form synapses. At earlier stages, pesticide exposure had little effect on cell survival. We then examined the effect of organophosphate exposure on neuronal morphology and architecture. Interestingly, the toxicity of the organophosphate pesticide diazinon appears to be independent of acetylcholinesterase inhibition. Together these data demonstrate that organophosphate exposure adversely affects neuronal development and highlights the importance of understanding the neurodevelopmental effects of USDA approved pesticides.

Title: Noggin inhibits bmp signaling in oligodendrocyte progenitor cells to repress transdifferentiation into astrocytes.

Authors: *H. STRASBURGER[1], L. KIRBY[2], J. SCHOTT[2];
[1]Johns Hopkins Hosp., Baltimore, MD; [2]Johns Hopkins Neuroimmunology, Baltimore, MD

Abstract: Multiple Sclerosis (MS) is a demyelinating disease of the central nervous system involving inflammation and neurodegeneration. In MS, the oligodendrocytes die off and axons are demyelinated. One possible therapeutic for MS is to induce more efficient remyelination of axons by targeting endogenous oligodendrocyte progenitor cells (OPCs) to replenish mature oligodendrocytes lost as a result of disease. In order to induce endogenous remyelination, the signaling factors surrounding oligodendrocyte differentiation and maturation must be investigated. We hypothesized that within an inflammatory environment, some OPCs may leave the oligodendrocyte lineage and instead transdifferentiate to become astrocytes. It has been observed in MS patients that there is a reduced production of noggin, a BMP inhibitor, and disregulated levels of BMPs. BMP binds to receptors BMPR1 and BMPR2 leading to Smad signaling within the cell. SMAD 1/5/8/ is phosphorylated once the BMPRs dimerize and binds to Smad4 to translocate to the nucleus to act as a transcription factor. If BMP signaling leads to increased glial fibrillary acidic protein (GFAP), an astrocyte specific protein, OPCs could potentially leave the oligodendrocyte lineage and transdifferentiate into astrocytes. Increased levels of astrocytes could further inflammation and neurodegeneration. Our results show that in rat OPC cultures the presence of noggin astrocyte contamination is greatly reduced in comparison to cultures without noggin. Using PDGFαR-CreER;Rosa26-eYFP mice we isolated OPCs at P5 and tracked OPC Cell fate in vitro with and without noggin. It was found that in the presence of noggin, transdifferentation of OPCs into astrocytes was inhibited, whereas without noggin 15% of the OPCs had left the oligodendrocyte lineage to become astrocytes as determined by immunocytochemistry. The same PDGFαR-CreER;Rosa26-eYFP mice were used to determine if transdifferentiation occurs in vivo. Mice were fed cuprizone for 6 weeks and a cocktail of BMP4/5 was administered through an osmotic pump into the brain. It was observed that at areas near the cannula insertion into the cortex OPCs had transdifferentiated into astrocytes. In addition, significant gliosis was observed near the injection site. These results suggest that BMP plays a role in determining OPC fate and gliosis. We are beginning to elucidate the Noggin-BMP balance in vivo to determine its affect on both astrocytes and OPC differentiation.

Title: Neuroprotective effect of melatonin in experimental optic neuritis in rats

Authors: *M. L. ARANDA, M. F. GONZALEZ FLEITAS, M. I. KELLER SARMIENTO, M. S. CHIANELLI, P. H. SANDE, D. DORFMAN, R. E. ROSENSTEIN;
CEFyBO - CONICET, Buenos Aires, Argentina

Abstract: We have developed a new experimental model of optic neuritis (ON) through the microinjection of bacterial lipopolysaccharide (LPS) into the optic nerve, which reproduces central features of human ON. The aim of this work was to analyze the effect of melatonin (MEL) on the optic nerve axoglial alterations induced by experimental ON. For this purpose, LPS (1 μl, 4.5 μg) was injected in one optic nerve from adult male Wistar rats, while the contralateral optic nerve was injected with vehicle. One group of animals received a subcutaneous pellet of MEL (20 mg) one day before LPS or vehicle injection which was replaced at 15 days, and another group was submitted to a sham procedure. In another set of experiments, the pellet of melatonin was implanted at 4 days post-injection of LPS or vehicle. The effect of melatonin was analyzed at 21 days post-injection in terms of: i) visual pathway function (visual evoked potentials (VEPs)), ii) anterograde transport from the retina to the superior colliculus (intravitreal injection of cholera toxin β-subunit), iii) pupil light reflex (PLR), iv) microglia/macrophages (by Iba-1 and ED1 immunoreactivity), v) astrocytes (by glial fibrillary acid protein-immunostaining), vi) axon number (by toluidine blue staining), vii) demyelination (by luxol fast blue staining), viii) retinal ganglion cells (RGCs) number (by Brn3a immunoreactivity), and iv) optic nerve lipid peroxidation (TBARS). LPS induced a significant decrease in VEP amplitude and PLR, a reduction in retinal anterograde transport, an increase in Iba-1 and ED1 immunoreactivity, astrocytosis, demyelization, an increase in lipid peroxidation, and RGC loss. The pre-treatment with MEL significantly prevented all these alterations. The post-treatment with MEL significantly preserved VEP amplitude and PLR. The treatment with melatonin prevented functional and histological alterations and diminished the vulnerability of RGC to the deleterious effects of experimental ON, probably through an antioxidant mechanism. Therefore, these results indicate that melatonin could be a promissory resource in the management of ON.

Title: Serum factors as predictors of interferon-alpha (IFN-alpha)-induced depression

Authors: *A. BORSINI, P. ZUNSZAIN, C. PARIANTE, S. THURET;
King's Col. London, London, United Kingdom

Abstract: IFN-α is the standard treatment for hepatitis C virus (HCV) infection, which causes high rates of depression. However, the biological factors that predispose an individual to the occurrence of depression are still unknown. Previous data have reported an alteration in the serum level of inflammatory markers in depressed, when compared with non-depressed patients. There is in fact evidence for serum factors to penetrate the blood brain barrier and modulate different brain signalling. Our study proposes to investigate whether co-incubation of human hippocampal progenitor cells (HPCs) with serum from IFN-α-treated HCV patients differently affect cell biology, when comparing serum from patients who will and will not later develop depression. Serum samples were collected at baseline, before the IFN-α treatment begins (treatment week (TW) 0) and at TW4 from 33 HCV patients; 9 of these patients later developed IFN-α-induced depression. The multipotent human hippocampal progenitor cell line HPC03A/07 was used to evaluate the effects of serum. Cells were co-incubated with serum samples under proliferating conditions for 2 days, followed by differentiating conditions for 7 days. During proliferation, apoptotic cells were evaluated by immunostaining with caspase 3 (CC3), whereas neuronal differentiation was assessed with doublecortin (DCX). Treatment with TW0 serum from depressed patients increased the percentage of CC3+cells ($U=49.5$, $p<0.05$), when compared with serum from non-depressed. However, there was no difference in the percentage of DCX+cells ($U=81$, $p=0.3$) between the two groups. In contrast, treatment with TW4 serum from non-depressed patients increased the percentage of DCX+cells ($U=56$, $p<0.05$), when compared with depressed. However, there was no significant difference in the percentage of

CC3+cells (U=100, p=0.8) between the two groups. Indeed, the increase in the percentage of DCX+cells was significantly higher upon treatment with serum samples from non-depressed than from depressed patients, when comparing TW4 with TW0 ($F(1,31)=6.5$; $p<0.05$). No significant difference was reported in the percentage of CC3+cells between depressed and non-depressed patients, when comparing TW4 with TW0 ($F(1,31)=0.8$; $p=0.4$). Our findings show that blood factors contained in serum of HCV patients who will later develop depression modulate both the process of apoptosis and neuronal differentiation. Future analyses should allow for the detection of serum factors involved in the alteration of cell death and neurogenesis, which may contribute to the advancement of novel therapeutic strategies for the prevention of IFN-α-induced depression.

Abstract: Inflammation is a common neuropathological feature in multiple sclerosis (MS) and EAE (experimental allergic encephalomyelitis), the most widely used animal model of MS. However, very early molecular signature of neuroinflammation in EAE is still obscure, such as the potential link between tissue alterations and peripheral biomarkers. In order to elucidate these points, in the present study we investigated molecular mediators of neuroinflammation and demyelination in the tissue (SC), CSF and plasma in female Dark-Agouti rats during early presymptomatic EAE, using high-throughput technologies for gene expression and protein assays. At 1, 5, 8, 11 and 18 day post-immunization (DPI), EAE rats were sacrificed and samples were collected. Our results indicate that the profile of neuroinflammation and demyelination

biomarkers is dramatically changed during the early phase of EAE in tissue, CSF and plasma. In particular, we have identified the regulation of the chemokine colony stimulating factor 1 (CSF1) at 1 DPI in EAE groups compared with control, that was decreased in tissue (mRNA, P=0.0064), decreased in CSF and increased in plasma (protein, P=0.0006). It was then attempted to identify the cell type producing CSF1 in the CNS by double labeling immunohistochemistry experiments approach, and we found that at 1 DPI CSF1 is expressed by oligodendrocytes and astrocytes in EAE animals, while at 11DPI (acute phase) only astrocytes express CSF1. Overall our findings suggest an early role of CSF1 in the course of MS pathology, and a potential, new target for MS.

Title: Persistent cytokine production induced in the cerebral meninges in a rat model of MS gives rise to chronic cortical pathology

Authors: ***R. REYNOLDS**, R. JAMES, E. BROWNE, L. FUENTES, N. MAZARAKIS; Imperial Col. London, London, United Kingdom

Abstract: The progressive phase of multiple sclerosis (MS) is characterised by accumulating grey matter (GM) pathology, including demyelination, neuronal and axonal damage and loss. Cortical demyelination is closely associated with the presence of immune cell infiltrates in the meninges, including lymphoid-like tissue development. Analysis of isolated meninges of secondary progressive MS cases has shown increased gene expression for the pro-inflammatory cytokines: tumour necrosis factor (TNF), lymphotoxin-α (LTα) and interferon-γ (IFNγ); and for the chemokines CXCL9 and CXCL13. In order to test the hypothesis that chronic production of pro-inflammatory cytokines in the meningeal compartment and diffusion into underlying GM can drive MS GM pathology, we stereotactically injected HIV-1 based VSV-g pseudotyped lentiviral transfer vectors into the sagittal sulcus (SS) of DA rats to deliver continuous transgene expression (TNF + IFNγ or LTα + IFNγ) in the meninges in a chronic manner. A neuropathology analysis was conducted at time points up to 3 months, together with RT-PCR to determine changes to TNF receptor-1 (TNFR1) signalling. Efficient transduction of meningeal cells resulted in cytokine expression for up to 3 months. Injection of vectors for TNF or LTα, in

combination with IFNγ, induced the formation of large immune cell aggregates in the meninges by 28 dpi, which remained at 3 months, containing CD4+ and CD8+ T-cells, CD79a+ B-cells and Iba1+ macrophages. These aggregates extended the length of the SS and across the surface of the cortex. Subpial demyelination was accompanied by widespread microglial activation underlying these cellular aggregates. Demyelination was increased in rats pre-immunised with a low dose of myelin protein MOG. A decrease in neurofilament expression in regions with subpial demyelination was present along with signs of neuronal stress indicated by Fluorojade-C staining of layer II-IV neurons. TNF/TNFR1 interaction can initiate cell death by activating pathways involved in necroptosis. TNF and IFNγ vector injected animals at 28 dpi showed an increase in expression of TNFR1 and downstream necroptotic genes and proteins, RIP3 and MLKL and their phosphorylated derivatives, compared to eGFP vector control animals. RIP3+ and MLKL+ immunopositive cells with the morphology of neurons were present in TNF + IFNγ vector injected animals. Our results suggest that TNF and LTα in the presence of IFNγ are potent inducers of meningeal inflammation and can activate TNF signalling pathways in cortical cells leading to neuronal death and subpial demyelination and thus may contribute to clinical progression in MS.

Title: Beneficial effects of nimodipine in EAE

Authors: *A. SCHAMPEL[1], S. KUERTEN[2];
[1]Anat. and Cellbiology, [2]Anat. and Cell Biol., Univ. of Wuerzburg, Wuerzburg, Germany

Abstract: Common therapeutic strategies in multiple sclerosis (MS) research aim at attenuating the immune response but do not provide persistent prevention of neurodegeneration. To gain insight into the underlying pathomechanisms of neurodegeneration and axonal pathology experimental autoimmune encephalomyelitis (EAE) is widely used as animal model for MS. In our study EAE was induced in SJL/J mice by subcutaneous injection of MP4 in complete Freund´s adjuvant. Immunization with this myelin antigen leads to a relapsing-remitting form of

disease. After immunization mice were observed daily for clinical symptoms and rated according to the common EAE-scoring system. The L-type calcium channel antagonist nimodipine is known to induce beneficial effects on cognitive performance, aging and on local vascularization of the central nervous system. However the effect of nimodipine on inflammatory-mediated neurodegenerative diseases has not been well studied yet. This study is the first to examine the effect of long-term treatment with nimodipine in a relapsing-remitting form of EAE. Our data show that the course of EAE was significantly reduced in nimodipine-treated mice compared to vehicle-treated littermates. Attenuation of clinical symptoms was reflected by less nerve fiber pathology and enhanced remyelination in ultrastructural analyses of the spinal cord. We observed several ways how nimodipine could favor remyelination in EAE, organotypic spinal cord culture and cell culture. Those mechanisms are still investigated but our results already indicate that nimodipine might be an important tool for therapeutic strategies.

Title: Altered functional Connectivity of striatal subregions in patients with multiple sclerosis

Authors: ***F. CUI**[1,2], L. ZHOU[2], K. JORGENSON[1], Z. WANG[1], Y. YU[2], Y. GAO[2], J. KONG[1]; [1]Massachusetts Gen. Hospital/Harvard Med. Sch., Charlestown, MA; [2]Dongzhimen Hosp., Beijing, China

Abstract: Introduction The striatum, a component of the basal ganglia, is involved in diverse functional domains including movement, cognition, emotion and reward. Recently, studies have shown that the striatum is also involved in the neuropathology of multiple sclerosis (MS). In this

study, we systemically compared the rsFC of striatal subregions between MS patients and matched healthy controls.
Methods Multiple sclerosis patients in the remission stage and healthy controls matched on age and gender were recruited for this study. Each subject participated in an identical fMRI scanning session using a 3T Siemens MRI system, in which 10-minute resting state fMRI data were collected. Seed-based rsFC was analyzed with CONN. We subdivided striatal subregions into the following 6 seed regions: dorsal caudate (DC), ventral caudate (superior) (VSs), ventral caudate/nucleus accumbens (inferior) (VSi), dorsal rostral putamen (DRP), dorsal caudal putamen (DCP), and ventral rostral putamen (VRP). A threshold of voxelwise $p< 0.005$ and $p< 0.05$ FDR corrected was applied.
Results Twenty MS patients and 15 healthy controls completed the study. The mean age of subjects was 36.97 ± 12.01 (mean ± SD). There were no significant differences in age and gender at baseline. The rsFC analysis showed that compared to the healthy controls, the MS patients produced significantly greater rsFC between 1) left DC and left precuneous, bilateral precentral, postcentral gyrus, and left parahippocampus; 2) left DCP and left cerebellum, middle frontal gyrus, and supramarginal gyrus; 3) left VSs and right lateral occipital cortex, middle temporal gyrus, and angular gyrus; 4) right VSs and left hippocampus, and parahippocampal gyrus. In addition, we found significant decreases in rsFC between 1) left DC and right cerebellum, left middle frontal gyrus (premotor), right parahippocampus; 2) right DC and right thalamus, insular, putamen, 3) right VRP and bilateral middle frontal gyrus (premotor), precentral gyrus, left superior frontal gyrus; 4) left VSs and left middle frontal gyrus (premotor), middle temporal gyrus; 5) right VSs and right middle prefrontal cortex.
Conclusion We identified a number of intriguing, statistically significant changes in resting state connectivity of the striatum subregions between MS patients and healthy controls. Our results suggest that different subregions of the striatum, especially dorsal caudate, putamen and ventral putamen, play important roles in movement regulation and modulation in MS patients.

Title: The effect of ONO-2952, a novel translocator protein 18 kDa antagonist, in a mouse model of multiple sclerosis

Authors: M. ISHISAKA, T. KOMIYA, T. KITAJIMA, *A. KISHI, S. KATSUMATA;
ONO Pharmaceut. Co., Ltd, Osaka, Japan

Abstract: Background: Translocator protein 18 kDa (TSPO) is localized in the outer mitochondrial membrane of many cell types such as reactive astrocyte and its expression is found to be up-regulated under various pathological conditions such as inflammation, mechanical lesions, neurological diseases, and cancer. In this study, we investigated the effect of ONO-2952 in the mouse model of multiple sclerosis (MS), experimental autoimmune encephalomyelitis (EAE).
Methods: EAE was induced in 8-week-old female C57BL/6J mice by injecting an emulsion of 200 μg of Myelin Oligodendrocyte Glycoprotein (MOG35-55) peptide in Freund's Complete Adjuvant (FCA) containing 500 μg of heat-inactivated M. tuberculosis (H37RA) subcutaneously on flank (Day 0). In addition, 200 ng of pertussis toxin (PTX) was intravenously injected on the same day as MOG-FCA, and a second PTX injection was administered 48 h later (Day 2). ONO-2952 (10 and 30 mg/kg/day) or vehicle (0.5% methylcellulose) were orally administered once a day for 30 days from the day before MOG-FCA injection. Mice were monitored daily for clinical signs of EAE and scored as follows: 1, flaccid tail; 2, weakness of hind limbs; 3, paralysis of both hind limbs; 4, paralysis of all limbs; and 5, moribund. On Day 29, mice were anesthetized and blood and spinal cord were collected. Immunostaining was performed using L4-L5 spinal cord sections to investigate the activation of astrocyte and microglia cells.
Results: ONO-2952 30 mg/kg/day ameliorated the daily neurological score and significantly improved the accumulated neurological score compared with vehicle-treated group. On Day 29, the numbers of GFAP-positive astrocyte and Iba1-positive microglia were increased in the spinal cord and ONO-2952 significantly decreased the population of GFAP-positive astrocyte and Iba1-positive microglia in a dose-dependent manner. There were no significant changes in the numbers of peripheral lymphocytes and neutrophils in ONO-2952-treated group.
Conclusions: These observations suggest that the novel TSPO antagonist, ONO-2952, is protective in the mouse model of MS, and a possible mechanism involved in the effect of ONO-2952 is to inhibit glial cell activation. ONO-2952 could be a potential new therapeutic option for MS without affecting peripheral immune cells.

Title: Local administration of TH2 cells into the CNS ameliorates the inhibitory effects of IFNg on remyelination

Authors: *L. A. KIRBY, M. SMITH, J. SCHOTT, P. CALABRESI;
Neuroimmunology, Johns Hopkins, Baltimore, MD

Abstract: Multiple sclerosis (MS) is an immune mediated demyelinating disease of the CNS. One potential cause of remyelination failure is chronic inflammation, therefore understanding the molecular mechanisms by which CNS inflammation inhibits the oligodendrocyte precursor cells (OPC) is important. While effector T-cells of the TH1 and TH17 phenotype are understood to be critical for the pathogenesis of MS, effector T-cells of the TH2 phenotype may have an opposing role by promoting remyelination and repair especially in an inflammatory setting. To investigate the role of TH2 cells we utilized the GFAP/tTA; TRE/IFNg transgenic mouse line in which CNS expression of IFNg from GFAP positive astrocytes is achieved upon doxycycline withdrawal. In order to determine whether TH2 cells promote remyelination after cuprizone induced demyelination we first directly administered TH2 cells (glatiramer reactive cells) into the CNS via intraventricular microinjection. In three separate experiments remyelination was significantly improved in TH2 injected mice compared to PBS injected control animals (mean percent difference = 18.91; p-value = 0.0107) as determined by black gold staining in corpora callosa tissue. Interestingly, the TH2 effect of improved remyelination was only detected in cuprizone fed mice induced to express IFNg in the CNS and there was no significant difference between TH2 and control mice in which IFNg expression was suppressed. The fact that TH2 cells can reproducibly overcome the strong and potent inhibitory effect of IFNg and promote remyelination is notable. While it remains controversial whether peripheral administration of TH2 cells are able to cross the intact BBB and accumulate in the CNS, we have been unable to detect a CD4+ cell population 14 days after adoptive transfer into cuprizone fed GFAP/tTA; TRE/IFNg mice. In order to further probe the mechanisms by which TH2 cells are mediating their effect, we are examining a wide variety of cytokines and neurotrophic factors including IL-4 and BDNF, an in vitro OPC differentiation assay. While only modest effects on OPC differentiation were observed in the IFNg/IL-4 co-treatment paradigm as determined by MBP mRNA and protein expression. Future work will be directed at elucidating the potential role of

BDNF and other factors, both *in vitro* and *in vivo* using the GFAP/tTA; TRE/IFNg transgenic mice. Further work in identifying the mechanism could yield a novel therapeutic target for MS.

Title: Astrocyte remodeling precedes extracellular matrix modifications in the glial lamina of mice with glaucomatous optic neuropathy

Authors: *R. A. FISCHER[1,2], H. L. MALLARO[3], E. S. BUYS[4,5,6,7], R. M. SAPPINGTON[1,3]; [1]Dept. of Pharmacol., [2]Pharmacol. Grad. Program, Vanderbilt Univ., Nashville, TN; [3]Vanderbilt Eye Inst., Vanderbilt Univ. Med. Ctr., Nashville, TN; [4]Anesthesia Ctr. for Critical Care Res., [5]Dept. of Anesthesia, [6]Critical Care and Pain Med., [7]Dept. of Ophthalmology, Massachusetts Gen. Hosp. and Harvard Med. Sch., Boston, MA

Abstract: Glaucoma is one of the leading causes of irreversible blindness in the world and results from degeneration of retinal ganglion cell (RGC) axons in the optic nerve. The two main risk factors are advanced age and elevated intraocular pressure (IOP). The optic nerve head (ONH) is considered the primary site of injury to RGC axons and contains the glia lamina that is comprised of astrocytes and demarcates the transition between unmyelinated and myelinated segments of RGC axons. ONH astrocytes provide structural support for RGC axons, in part by mediating extracellular matrix (ECM). Elevated IOP can alter the elasticity of the ONH and promote further progression of RGC degeneration. To determine how temporal changes in IOP alter astrocyte and ECM remodeling in glaucoma, we examined changes in the ECM as well as cytoarchitecture of astrocytes in the ONH and myelinated optic nerve (mON) of three mouse

models of glaucoma. To examine short-term IOP elevations, we utilized an inducible model (Microbead Occlusion Model). For long-term IOP elevations, we examined two chronic models, soluble guanylate cyclase α_1 deficient (sGCα_1-/-) and DBA/2J mice, in which IOP elevations are age-dependent. To measure changes in astrocyte cytoarchitecture, we labeled actin (phalloidin) and intermediate (GFAP) filaments and quantified changes in filament organization. In corresponding tissue sections, we performed immunolabeling and quantification of ECM components, including collagen I, collagen IV, TGF-β, and thrombospondin. Disorganization of actin and intermediate filaments in both ONH and mON astrocytes was apparent after short-term elevation of IOP (4 weeks) and persisted for long-term elevations (2-4 months). Actin labeling was significantly reduced in ONH astrocytes across all models ($p < 0.05$). In the ONH of all models, fiber orientation in astrocytes shifted from perpendicular to parallel, with respect to RGC axon bundles ($p < 0.05$). These changes in ONH astrocytes were accompanied by decreased collagen I and collagen IV in the ECM of DBA/2J and sGCα_1-/- mice, respectively ($p < 0.05$). In the mON, astrocyte reorganization coincided with decreased collagen IV and TGF-β in the ECM of sGCα_1-/- and DBA/2 mice, respectively ($p < 0.05$). Short-term elevations in IOP did not alter ONH ECM and only increased thrombospondin composition in the mON ($p < 0.05$). Our data suggest that elevated IOP induces relatively early and persistent astrocyte remodeling. Changes in ECM composition noted in chronic models could contribute to increased elasticity of the ONH and are likely preceded by astrocyte remodeling, as evidenced by the lack of ECM changes in the ONH following short-term IOP elevation.

Title: Cuprizone treatment, toxic demyelination, and the blood-brain barrier

Authors: *J. SHELESTAK[1], R. CUKELJ[2], N. SINGHAL[1], J. MCDONOUGH[1], E. FREEMAN[1], R. CLEMENTS[1];
[1]Biomed. Sci., [2]Kent State Univ., Kent, OH

Abstract: The cuprizone animal model is widely used to study toxic demyelination in the central nervous system. Cuprizone is a copper chelator that causes selective oligodendrocyte death leading to consistent demyelination. Unlike most demyelinating diseases such as MS, existing

studies suggest the cuprizone model appears to maintain an intact blood-brain barrier (BBB). In the present study, we aim to assess the integrity of the blood brain barrier after 6 week administration of cuprizone. Mice were fed with cuprizone supplemented in the diet for 6 weeks and imaged using MRI every two weeks starting on week 0. Evidence of demyelination and ventricle enlargement was examined with T1, T2, and diffusion weighted protocols. The mice were sacrificed after 6 weeks of treatment and tissue sections were immunofluorescently stained and imaged using confocal microscopy. Tissue was stained for neurons, myelin, astrocytes, microvessels, oligodendrocytes and immune cells and analyzed to assess the integrity of the blood-brain barrier. Cuprizone treatment caused significant weight loss, as well as a measurable change in ventricle size seen after 6 weeks of treatment. Myelin staining intensity was clearly reduced in distinct brain regions including primary motor cortex, corpus callosum, and striatum. There was a significant increase in detectable astrocytes, as well as alterations in both astrocytic and microglial morphologies indicative of cellular activation. BBB integrity was assessed using computational image analysis techniques to investigate whether cuprizone treatment is associated with morphological changes indicative of BBB disruption. Here we report the status of BBB integrity and its relationship to demyelinating activity in the cuprizone animal model.

Title: Increased expression of specific NKG2D ligand in a mouse model of multiple sclerosis

Authors: *L. LEGROUX, S. VERSTRAETEN, G. DEBLOIS, A.-N. MOHEBIANY, D. BEAUSEIGLE, N. ARBOUR;
CRCHUM, Univ. De Montréal, Montreal, QC, Canada

Abstract: **Introduction**: Multiple sclerosis (MS) is considered the prototypic inflammatory disease of the central nervous system (CNS). Lesions in the CNS of MS patients are characterized by myelin sheath destruction, oligodendrocyte death, axonal and neuronal damage, and activation of glial cells. It is well established that the immune system participates in the pathogenesis of MS. Nevertheless, the contribution of specific immune mediators to injury

remains to be defined. NKG2D is an activating receptor expressed by numerous immune effector cells including subsets of CD8 and CD4 T cells. NKG2D binds to various ligands (NKG2DL), which include RAE-1(alpha to epsilon), MULT1, and H60 (a-c) in mice. NKG2DL are induced by environmental triggers (e.g. inflammation) suggesting that these proteins alert the immune system to abnormal cells. Our laboratory has previously showed that oligodendrocytes express at least one NKG2DL in MS lesions but not in control brains. Moreover, CD8 T cells in MS lesions are detected in close proximity to NKG2DL expressing cells. We have also established that disruption of the NKG2D-NKG2DL interaction inhibits killing of human oligodendrocytes by activated immune effector cells in vitro. One group showed that blockade of NKG2D diminished disease severity in the MS mouse model: experimental autoimmune encephalomyelitis (EAE). Overall, these results imply that NKG2D-NKG2DL interaction can contribute to the pathogenesis of MS and its animal model EAE. However, whether specific NKG2DL are upregulated by CNS cell subsets in vivo during the development of EAE and could potentially be targeted is still unresolved.
Methodology: Using well established EAE mouse models, we assessed qualitatively and quantitatively the expression of NKG2D and NKG2DL during different stages of the development of EAE. We used flow cytometry, qRT-PCR, western blot and immunohistochemistry approaches.
Results: We observed that MULT-1, one specific ligand of NKG2D, is upregulated in the CNS of EAE mice and such elevated expression correlates with disease severity. Moreover, MULT-1 is detected on neurons, astrocytes and endothelial cells and is released in the extracellular matrix and cerebrospinal fluid during EAE. In contrast, expression of other ligands does not vary throughout disease. Finally, we also observed a greater proportion of CNS infiltrating CD4 and CD8 T cells expressing NKG2D compared with cells from other organs. Finally, the elevated NKG2D expression on CD8 T cells correlates with augmented effector functions (IFNγ, GM-CSF and granzyme B production). Our results suggest that NKG2D and specific ligands could play a role in the pathogenesis of MS.

Title: Increased gabaergic inhibition through α5-subunit containing $gaba_a$rs contributes to impaired hippocampal synaptic plasticity in eae

Authors: *L. G. KAMMEL[1], W. WEI[2], R. VOSKUHL[3], T. O'DELL[2];
[1]Molecular, Cellular, and Integrative Physiol. Grad. Program, [2]Dept. of Physiol., [3]Dept. of Neurol., David Geffen Sch. of Medicine, UCLA, Los Angeles, CA

Abstract: Cognitive impairment affects 40-65% of multiple sclerosis (MS) patients. Using the mouse model of MS (experimental autoimmune encephalomyelitis, EAE), we investigated if disease-induced functional deficits in the hippocampus underlie this impairment. We found that the induction of LTP was significantly reduced in the hippocampal CA1 from EAE mice (fEPSPs were potentiated to 135.9 ± 4.3% of baseline in controls, n = 5, compared to 119.8 ± 2.6% in EAE, n = 6, $p < 0.05$) using 150 pulses of 5 Hz presynaptic fiber stimulation. Also, tonic inhibition mediated by extrasynaptic GABA receptors was strongly enhanced in CA1 pyramidal cells from EAE mice (currents were 0.43 ± 0.07 pA/pF in controls, n = 13 and 0.76 ± 0.06 pA/pF in cells from EAE mice n = 28, $p < 0.01$). Since enhanced tonic inhibition could oppose the induction of LTP, and tonic inhibition in the hippocampal CA1 is mediated by α5-subunit (GABRA5) containing $GABA_A$Rs, we next investigated whether blocking the GABRA5-sensitive tonic current could ameliorate the deficit in LTP during EAE. Consistent with this hypothesis, 150 pulses of 5 Hz stimulation in the presence of the GABRA5 inverse-agonist L-655,705 abolished differences in levels of LTP in slices from control versus EAE mice (fEPSPs were potentiated to 138.4 ± 5.2% of baseline in controls, n = 5, and 136.6 ± 5.5% in slices from EAE mice, n = 5). It had been reported that GABRA5 expression is upregulated in post-mortem hippocampal tissue from MS patients, therefore we next investigated if altered expression of GABRA5 could underlie the enhanced tonic current in EAE. Indeed, GABRA5 plasma membrane (PM) expression was significantly upregulated in the EAE hippocampus (GABRA5/FLOT-1: EAE, n=6, showed 157.9 ± 12.0% expression of controls, 100 ± 8.8%, n=5, $p< 0.01$). Finally, because reduced GABA uptake could also contribute to the enhanced tonic current, we additionally investigated if the PM expression of neuronal (GAT-1) or astrocyte (GAT-3) GABA transporters was altered in EAE. While GAT-1 showed no differential PM expression, GAT3 PM expression was significantly decreased in the EAE hippocampus (GAT3/FLOT-1: EAE, n=6, showed 69.4 ± 6.2% expression of controls, 100 ± 2.8% n=5, $p< 0.01$). Together these data suggest that targeting altered GABAergic neurotransmission, mediated by the dysregulation of α5-subunit containing $GABA_A$Rs and of astrocyte GABA transporters, warrants investigation as a strategy for treating hippocampal-dependent cognitive impairments in MS.

Title: molecular MRI reveals pselectin protein as a predictive marker in experimental autoimmune encephalomyelitis

Authors: *R. M. MACREZ[1], A. QUESNAULT[2], A. QUESNAULT[2];
[1]GIP Cyceron Inserm U919, Caen, France; [2]INSERM U919, CAEN, France

Abstract: Developing new strategies for detection of disease activity in multiple sclerosis is important to ameliorate the diagnosis and follow-up of this pathology. For that, we used microparticles of iron oxide (MPIO) coupled to an antibody specific to the p-selectin protein and a MRI sequence triggered with the animal breathing. In this study, we aimed to demonstrate that molecular magnetic resonance imaging (MRI) specific to p-selectin protein is able to detect the pathological events that take place in the spinal cord of **chronic and relapsing experimental autoimmune encephalopathy (EAE)** in mice. More interestingly, we show here that this MRI technique can **predict the apparition of EAE**. Further, we used Evans blue ex-vivo optical imaging combined with immunostaining to visualise blood spinal cord barrier (BSCB) opening and immune cell infiltration. We show that with a single injection of microparticles, this innovative MRI technique can reveal the BSCB opening together with the immune cell infiltration. Our data suggest that molecular MRI targeting-p-selectin allows non-invasive measurement of vascular inflammation and thus, could be used as additional information inaccessible to conventionally used MRI techniques.

Title: Estrogen receptor beta (ERβ) on $CD11c^+$ cells is required for ERβ-ligand mediated neuroprotection during experimental autoimmune encephalomyelitis

Authors: *R. KIM[1,2,3], N. ITOH[3], A. HOFFMAN[3], R. KOVASH[3], R. VOSKUHL[3];
[2]Molecular, Cell. and Integrative Physiol. Grad. Program, [3]Multiple Sclerosis Program and Dept. of Neurol., [1]UCLA, Los Angeles, CA

Abstract: Multiple sclerosis (MS) is an autoimmune disease of the central nervous system (CNS). EAE is the most widely used animal model of MS and we have previously shown that ERβ-ligand treatment is neuroprotective during disease. Also, ERβ-ligand treatment can exert anti-inflammatory effects on CNS resident microglia and dendritic cells (DC). However, whether these cell types are directly targeted by ERβ-ligand treatment during EAE remains unknown. Here, we used CD11c promoter to generate conditional knockout (CKO) mice of ERβ (CD11c-CKO-ERβ) using the *Cre-loxP* system. CD11c is known to be a marker for DCs, however, activated myeloid derived cells including microglia and macrophages may also express CD11c during EAE. We induced EAE in CD11c-CKO-ERβ mice and wildtype littermate control (CD11c-WT-ERβ) mice, with or without ERβ ligand treatment to determine if ERβ expression on these cells was critical for treatment-induced neuroprotection. Our results demonstrated that CD11c-WT-ERβ mice treated with ERβ-ligand had significant improvement in clinical disease, as well as protection from axonal and myelin loss in spinal cord, with no significant effect on levels of immune cell infiltration, and that this protection from disease was lost in CD11c-CKO-ERβ mice. Next we investigated whether ERβ-ligand treatment may have induced phenotypic changes (activation; MHCII, polarization; M1 – iNOS, M2 – Arg1) on CNS resident and infiltrated myeloid derived $Iba1^+$ cells during EAE. We observed that ERβ-ligand treated CD11c-WT-ERβ mice had reduced MHCII expression and M1 polarization, with no effect on M2 polarization, and that this ERβ ligand treatment effect on phenotype was lost in CD11c-

CKO-ERβ mice. Together these data indicate that protective effects of ERβ-ligand treatment during EAE are mediated through ERβ on $CD11c^+$ cells, and this entails reducing MHCII activation and iNOS expression on CNS resident and infiltrated myeloid derived $Iba1^+$ cells.

Title: Oligodendrocyte lineage tracing in a multiple sclerosis mouse model—a cuprizone-fed mouse transferred with myelin-reactive th17 cells.

Authors: *J. JIN, M. SMITH, D. HEO, M. POUDEL, D. TOSI, E. BAXI, D. BERGLES, P. A. CALABRESI;
Johns Hopkins Univ. Sch. of Med., Baltimore, MD

Abstract: Multiple sclerosis (MS) is an acquired inflammatory demyelinating disease of the central nervous system. It is known that failure of remyelination can lead to irreversible axonal damage. However, the mechanisms underlying remyelination failure are still unclear. Inflammation is a key factor in the initiation and persistence of MS. Understanding the response of oligodendrocyte precursor cells (OPC) during demyelination/remyelination in an inflammatory context may help identify strategies to facilitate remyelination and protect axons from damage.
In this study we used a PDGFaR-Cre:ROSA26-YFP double-transgenic mouse, which express inducible YFP in PDGFaR+ cells, to examine OPC proliferation, viability, and differentiation during demyelination and remyelination in an inflammatory environment. Mice were fed cuprizone (or normal chow) for four weeks followed by a transfer of myelin specific Th17 T-cells (or vehicle) (Baxi, et al.). Mice were recombined after three weeks of cuprizone treatment and were sacrificed 1 or 2 weeks after cuprizone cessation and cell transfer.
As previously shown, Black-Gold II staining showed more severe demyelination in the corpus callosum at 1 week post-transfer Th17 cells and impaired remyelination at 2 weeks in Cup+Th17

mice vs Cup-only. A week post-transfer, there were abundant CD3+ T-cells infiltrating the brain which were still proliferating at 2 weeks post-transfer in Cup+Th17 mice. These infiltrated T cells were more clustered at areas of impaired remyelination. The numbers of different oligodendrocyte lineage traced YFP+ populations were compared in the corpus callosum of Cup+Th17 mice with those of Cup-only mice. At 1 week, there were no CC1+ cells in the corpora callosa of both Cup+Th17 and Cup-only groups. YFP+ cells and PDGFaR+ OPC cells were significantly decreased in Cup+Th17 mice vs Cup-only mice. At 2 weeks, total YFP+ cells and mature oligodendrocytes (CC1+ and CC1+/YFP+cells) were decreased in Cup-Th17 mice. The percentage of pre-myelinating oligodendrocytes was higher in Cup+Th17 mice, indicating these cells did not develop into mature oligodendrocytes. These pre-myelinating oligodendrocytes might have their differentiation arrested and/or be targeted for apoptosis upon initiating differentiation by the infiltrating T-cells and their accompanying inflammation. The investigation into how these inflammatory cues and immune cells are involved in the remyelination failure of Cup+Th17 mice is ongoing. Our ultimate goal is to find targetable pathways to reduce the local CNS inflammation mediated inhibiton of OPCs in order to facilitate remyelination and thus protect axons from degeneration.

Title: Role of RhoA in T cell adhesion and migration in an experimental model of multiple sclerosis

Authors: *A. MANRESA ARRAUT, H. HASSELDAM, F. F. JOHANSEN;
Biotech Res. & Innovation Ctr., Kobenhavn N, Denmark

Abstract: Experimental autoimmune encephalomyelitis (EAE), an animal model of brain inflammation, shares essential clinical and pathological features with Multiple Sclerosis (MS). The main trigger of central nervous system (CNS) inflammation and demyelination in EAE is an activation of CD4+ T-cells in the periphery followed by infiltration into the CNS. The small GTPase RhoA regulates processes which are crucial for immune cell function such as actin

assembly, cytoskeleton plasticity and stress fiber formation, all involved in cell adhesion and migration.
The primary aim of this project is to investigate whether specifically knocking out the small GTPase RhoA in T-cells will impact their ability to induce disease. For this purpose we induced EAE in C57BL/6 mice lacking RhoA expression in T-cells. Our results show that $RhoA^{-/-}$ mice experience decreased disease incidence and severity, compared to their wild-type littermates. Mice heterozygous for the deletion of RhoA in T-cells ($RhoA^{+/-}$) present a similar disease pattern as their wild-type littermates. However, a milder form of the disease is observed, indicating that the presence of only one allele does not provide T-cells with a fully functional RhoA activity. Secondarily we plan to further investigate the role of RhoA in T-cells. We have set up an *in vitro* blood brain barrier model that will allow us to study the migratory capacity of the $RhoA^{-/-}$ T-cells across the brain endothelium. In parallel we have set up a proliferation assay to study if the lack of RhoA impacts T-cell proliferation after TCR stimulation, using both unspecific CD3-stimulation and MOG-specific stimulation. A thorough analysis of the integrin expression and cytokine production will be conducted in $RhoA^{-/-}$ T-cells using flow cytometry, multiplex immunoassays and cell binding assays.
Taken together, our data suggest that RhoA activity in T-cells plays an important role in onset and progression of EAE, which might be due to its role in leukocyte adhesion and migration.

Title: Strain differences in sensitivity to cuprizone induced demyelination

Authors: *Q. YU[1], R. HUI[1], Y. HUANG[2], A. KUSNECOV[3], C. F. DREYFUS[2], R. ZHOU[1]; [1]Chem. Biol., [2]Neurosci. and Cell Biol., [3]Psychology, Rutgers, Piscataway, NJ

Abstract: Multiple Sclerosis (MS) is a severe neurological disorder caused by demyelination of the central nervous system (CNS) and affects about 2.5 million people worldwide. However the molecular mechanisms underlying the pathogenesis of the disease remain unclear. We investigated the role of genetic differences in contributing to demyelination by using the cuprizone toxicity model with mice of different genetic background (CD1 and C57BL/6). We demonstrate using luxol fast blue (LFB) staining that exposure to diet containing 0.2% cuprizone treatment resulted in less severe demyelination in CD1 mice than C57BL/6 mice. With continuous cuprizone administration, demyelination in CD1 mice was not prominent until after 7 weeks of treatment, in contrast to C57BL/6 mice, in which demyelination was already prominent at week 4 of exposure. Concomitantly, immunohistochemical analysis of the cuprizone treated brain sections of the corpus callosum overlying the fimbria fornix demonstrated significantly more GST-pi+ oligodendrocytes in the CD1 mice relative to C57BL/6 mice. Moreover, CD1 mice exhibit fewer GFAP+ astrocytes and Iba1+ microglia. In order to rule out the issue of potential difference in diet consumption between strains, we measured food intake per body weight between CD1 mice and C57BL/6 mice and report no significant differences. Thus, genetic background factors appear to influence the susceptibility to cuprizone induced demyelination, and our findings might provide new insight into the detailed mechanism of the demyelination process.

Title: Interferon gamma-stimulated human dendritic cells produce promyelinating exosomes and replicate rodent studies

Authors: *K. M. PUSIC[1], L. WON[2], A. D. PUSIC[2], R. P. KRAIG[2];
[1]Dept. of Neurol., [2]Univ. of Chicago, Chicago, IL

Abstract: Multiple sclerosis (MS) and migraine are interrelated healthcare burdens which involve considerable negative impact. Spreading depression (SD), the underlying cause of migraine with aura and a well-accepted animal model for migraine, occurs with transient demyelination (1) and increased oxidative stress (2). This is similar to MS where damage to myelin and oxidative stress prevent remyelination.
We have developed a novel cell-based therapy - microRNA-containing (i.e., especially miR-219) exosomes from IFNγ-stimulated dendritic cells (SDC-Exos) - that for the first time remyelinates damaged rat brain (3) and prevents SD (4), perhaps by reducing oxidative stress. Given the uncertainty in translating rodent studies to human therapeutics, we are testing the possibility of producing human SDC-Exos to recapitulate the effects seen from rodent SDC-Exos .
Exosomes were produced from human dendritic cells (DCs) cultured from three sources: peripheral blood, cord blood and bone marrow. Our methods involve selective derivation of adherent immature DCs, which are then stimulated by IFNγ for collection of conditioned media three days later. Identity of DCs was confirmed by morphology and immunostaining (i.e., $CD11b^-$ for macrophages and $CD11c^+$ for DCs). Exosome isolation was confirmed via electron microscopy (i.e., ~100 nm vesicles) and western blot for surface marker CD63. All three sources were successfully differentiated into DCs and produced exosomes. We found that human bone marrow-derived SD-Exos triggered a significant increase (~170%) in myelin basic protein, a marker for myelin, three days after application to rat hippocampal brain slice cultures. This is consistent with the ~122% increase seen in these cultures after application of rat SD-Exos (3) that reached a peak of 150% at five days before returning to normal by seven days (Pusic AD, unpublished observations). Human SD-Exos also contained a significant (> 1000-fold increase versus exosomes derived from unstimulated human DCs) level of miR-219, a microRNA that is necessary and sufficient for promoting oligodendrocyte precursor cell differentiation (5). Also, SDC-Exos showed no evidence of microgliosis.
These results support the feasibility and utility of producing SDC-Exos from autologous and heterologous **human** DC sources as a novel therapeutic to mitigate the impact of neurodegenerative disorders involving myelin dysfunction and oxidative stress, without producing negative inflammatory sequelae.

Title: Anti-neuroinflammatory effect of VB037 in experimental autoimmune encephalomyelitis model

Authors: *H. LI, Y.-S. LO, K.-H. CHANG;
Neurol. Dept., Chang-Gung Mem. Hosp., Guishan Dist., Taoyuan, Taiwan

Abstract: Multiple sclerosis is an immune-mediated demyelinating disease of human central nervous system. The experimental autoimmune encephalomyelitis (EAE) model is the most commonly used experimental model for resembling multiple sclerosis. In the in-vitro study we prove the anti-neuroinflammatory effects of one testing drug, VB037, which is extracted from Chinese medicine. In the current study, we induct a monophasic form of EAE model in C57BL/6 mouse via immunization with myelin oligodendrocyte glycoprotein (MOG_{35-55}). We then initiate drug testing via intraperitoneal injection for 14 days. Drug responses are monitored by weight changes and EAE score (0-5) for clinical severity. Our preliminary data shows that VB037 has significant effects in prevention of weight loss and in EAE score severity deterioration. Western blot analysis and immunohistochemistry stain with anti-Iba1 antibody, a macrophage/microglia-specific calcium-binding protein, also confirm the same results. In conclusion, we demonstrate that using the EAE mouse model, VB037 may have anti-neuroinflammatory effects in postponing the disease onset and progression.

Title: AdipoR agonist, AdipoRon, decreases lipid accumulation and ameliorates the functions of myelin-laden macrophages

Authors: *X. SUN[1], Q. ZHOU[1], H. XIANG[1], A. LI[1], C. QIN[1], X. CHEN[2], Y. REN[3]; [1]Guangdong-Hong Kong-Macau Inst. of CNS Regeneration, Jinan Univ., Guangzhou City, China; [2]Inst. of Inflammation and Diseases, the First Affiliated Hosp. of Wenzhou Med. Univ., Wenzhou, China; [3]Dept. of Biomed. Sciences, Florida State Univ. Col. of Med., Tallahassee, FL

Abstract: Myelin-laden macrophages, resulting from phagocytosis of myelin debris by infiltration of bone marrow-derived macrophages, are abundantly present in demyelinating CNS injuries and diseases, such as spinal cord injury and multiple sclerosis. The accumulation of myelin debris in these macrophages induces neuroinflammation by stimulating the expression of pro-inflammatory factors, and impairing their phagocytic capacity. Lipids are major components of myelin debris; therefore, efficient efflux of myelin lipid may help ameliorate macrophage functions. Adiponectin is a protein hormone involved in metabolic processes that can increase cholesterol efflux from oxLDL-treated macrophages. In this study, we found that AdipoRon, a novel small molecule agonist of adiponectin receptors, could effectively decrease myelin lipid accumulation and suppress foam cell formation in myelin-laden macrophages in both time- and dose-dependent manners. Such effects were partially mediated by increased levels of ABCA1, but not ABCG1. AdipoRon also promoted M2 polarization of myelin-laden macrophages. Furthermore, AdipoRon treatment *in vitro* could ameliorate the functions of myelin-laden macrophages by inhibiting the production of pro-inflammatory factors as well as enhancing their phagocytosis of apoptotic cells. These data suggest that AdipoRon may be a promising therapeutic approach for the treatment of macrophage-mediated neuroinflammation in demyelinating CNS disorders.

Title: Interactions between stress-induced modifications of intestinal inflammation and the occurrence of EAE relapses.

Authors: *A. FOURNIER[1], M. NEUNLIST[2], D. VIVIEN[1], R. MACREZ[1], F. DOCAGNE[1]; [1]INSERM U919, Caen, France; [2]INSERM U913, Nantes, France

Abstract: Clinical observations have shown a link between acute stress and the occurrence of relapses in MS patients. Here, we show a repeated acute stress model (water avoidance stress) induces a twofold increase in the incidence of relapses in relapsing-remitting EAE in mice, together with an increase in intestinal permeability. We hypothesize that physiological stress induces an increase in intestinal permeability which would provide an immunological context favouring the occurrence of relapses. To test this, we developed an innovative molecular MRI imaging of gut inflammation. This technique allowed us to show that an intestinal inflammation occurs during EAE relapses. Further, we used a model of gut inflammation induced by dextran sodium salt (DSS) in EAE to check if intestinal inflammation can induce an increase in relapse incidence. Our data suggest that treating gut inflammation (pre/probiotics, micronutrients…) could prevent relapse occurrence and limit the effect of stress. This study should also help taking into account stress management in patient care. In addition, the innovative MRI techniques developed in this study could bring new advances in the diagnosis and prognosis of MS relapses by targeting gut inflammation.

Abstract: In multiple sclerosis (MS), soluble tumor necrosis factor (TNF) has been attributed detrimental functions, whereas transmembrane TNF promotes neurorepair primarily by activating TNF receptor 2 (TNFR2). Here we investigate the role of TNFR2 in microglia and peripheral monocytes/macrophages using novel cell-specific conditional knockouts in experimental autoimmune encephalomyelitis (EAE), a model of MS. We show that microglial TNFR2 ablation leads to early onset of EAE, with increased leukocyte infiltration in the central nervous system (CNS), T cell activation, and demyelination. TNFR2-ablated microglia shows a more pro-inflammatory phenotype, with dysregulation of genes controlling innate immunity and host defense. Conversely, monocyte/macrophagic TNFR2 ablation results in EAE suppression, with impaired peripheral T cell activation, and reduced CNS T cell infiltration and demyelination. Our work uncovers a dichotomy of function for TNFR2 in myeloid cells, with microglial TNFR2 providing protective signals to contain disease, and monocyte/macrophagic TNFR2 driving immune activation and EAE initiation. The complexity of TNFR2 function must be taken into account when targeting TNFR2 for therapeutic purposes in neuroinflammatory diseases.

Title: Mitoxantrone prevents disease relapse in a rat model of multiple sclerosis

Authors: *E. ANDRIAMBELOSON, J. BINDLER, C. NEVEU, L. BOURGOIN, L. GORJ, B. HUYARD, N. KADOUCI, F. LAUGA, E. POIRAUD, S. WAGNER;
NEUROFIT, ILLKIRCH, France

Abstract: Mitoxantrone (Novantrone) is an immunosuppressive drug that impacts both T and B cell proliferation. In 2000, mitoxantrone was approved by the FDA for the treatment of multiple sclerosis (MS). Indeed, clinical data suggests that the drug markedly reduces relapse rate in patients with very active relapsing remitting MS (relapses reduced by up to 70-80%) and significantly reduces the accrual of disability over 2 years in patients with relapsing remitting MS. However, there is no animal data showing the beneficial effect on the disease relapse when mitoxantrone treatment is initiated only after the occurrence of the first attack. The present study investigates the effect of mitoxantrone in a rat model of relapsing remitting experimental allergic encephalomyelitis. In this model, the disease relapse is observed after a short (4-5 days) and partial recovery period following the first attack. The severity of clinical disability during the relapse is comparable to that observed during the first attack. Continuous daily treatment with 0.5 mg/kg mitoxantrone initiated after the remittance from the first attack fully suppressed the course of disease relapse. The accrued disability score over the disease relapse period was significantly reduced. For comparison, preventive daily treatment with 0.5 mg/kg, initiated before the appearance of any clinical signs of the first attack, gave a 90% of the accrued disability score during the relapse period. Furthermore, the authors wanted to determine whether mitoxantrone might have a direct effect on CNS inflammation. The results showed that mitoxantrone does not prevent LPS-induced neuronal inflammation and death in a mixed glia-neuron culture which suggests the beneficial effect of the drug is not likely to be driven by a direct attenuation of inflammation on CNS-resident cells. A more plausible target of mitoxantrone for the herein observed in-vivo effect thus might be an immunomodulation of peripheral immune response.

Title: Therapeutic estrogen receptor beta (ERβ) ligands modulate peripheral cytokines and may be responsible for remyelination in a mouse model of multiple sclerosis.

Authors: *H. KARIM[1], J. HASSELMANN[1], N. YASUI[2], J. KATZENELLENBOGEN[2], S. TIWARI-WOODRUFF[1];
[1]Biomed. Sci., Univ. of California, Riverside, Riverside, CA; [2]Univ. of Illinois, Urbana, IL

Abstract: Estrogen receptor β (ERβ) ligands have been shown to induce remyelination in different mouse models of multiple sclerosis (MS). Recent work using the chronic myelin oligodendrocyte glycoprotein experimental autoimmune encephalomyelitis (MOG-EAE), has shown that different ERβ ligands (diarylpropionitrile (DPN), Indazole chloride (IndCl), WAY 202041 (WAY)) all demonstrate remyelination, but show differential immune effects in the periphery. Previous studies have shown that treatment with DPN confers remyelination without significant effects on inflammation, whereas IndCl confers neuroprotection and inhibits inflammation. Recent results from our group have shown similar neuroprotection with WAY without obvious effects on inflammation. Here, we wanted to compare the effect of these different ligands on peripheral cytokines and CNS immune cells. MOG-EAE was induced by standard protocols from the Tiwari-Woodruff lab. Flow cytometry and peripheral splenocyte cytokine analysis were performed on vehicle, prophylactic 17β-estradiol (E2) and therapeutic ERβ ligand-treated age and sex matched C57Bl/6 female mice. Vehicle treated EAE mice showed disease onset between 7-10 days. Positive control pre-E2 treated animals did not show any clinical disease. Unlike DPN-treated animals (similar onset of disease as vehicle-treated group), IndCl and WAY treatment delayed onset of EAE clinical symptoms. Day 21-post EAE flow analysis revealed an increasing trend in resting microglia and a significant decrease in macrophages in pre-E2 but not IndCl, WAY and DPN treated groups. A significant decrease in Th1 and Th17 CNS cells was observed only in pre-E2 treated groups. None of the treatments modified either the Th2 or the Treg CNS population. A decrease in splenic macrophages was observed with pre-E2 treatment. Interestingly, an increase in macrophages was observed in all ERβ ligand treated groups. Peripheral cytokine analysis revealed a reduction of IFNγ, interleukin (IL)-17, GM-CSF and IL-2 with an increase of IL-10 expression in IndCl and WAY treated EAE groups, similar to pre-E2 group. An interesting result was a significant increase of the chemokine CXCL1 (involved in oligodendrocyte proliferation and recruitment) in all ERβ ligand treated groups, with no change in E2 and vehicle groups. The present study indicates an intricate interplay between the peripheral and central immune systems that seems to be responsible for the remyelinating effects of ERβ ligand treatment during EAE. More studies including conditional gene knockouts are needed to address the relationship between immune modulation and neuroprotection by ERβ ligands.

Title: The contribution of dysfunctional hnRNP A1 and anti-hnRNP A1 antibodies to MS pathogenesis

Authors: *H. SALAPA, S. LEE, Y. SHIN, M. C. LEVIN;
Univ. of Tennessee Hlth. Sci. Ctr., Memphis, TN

Abstract: It is becoming evident that inflammation and neurodegeneration occur simultaneously but independently during multiple sclerosis (MS). Heterogeneous nuclear ribonuclear protein A1 (hnRNP A1) is an RNA binding protein (RBP) that shuttles between the nucleus and cytoplasm to modulate RNA metabolism. Nuclear import of hnRNP A1 is mediated by its nuclear localization sequence, M9. RBPs, including hnRNP A1, have been implicated in the pathogenesis of other neurological disorders. Common features of these disorders include altered mRNA transport functions, redistribution of RBPs, and the formation of pathogenic stress granules. Our lab has found that MS patients, in contrast to controls, make autoantibodies to hnRNP A1-M9. We hypothesized that hnRNP A1 might exhibit pathogenic features similar to other neurological disorders using *in vitro* and *in vivo* models of MS. Furthermore, we sought to determine whether anti-hnRNP A1-M9 antibodies might contribute to disease pathogenesis. For *in vitro* experiments, SKNSH cells were treated with T_h17 cytokines (IL-17A, IL-23) and examined for hnRNP A1 mislocalization. For *in vivo* experiments, female C57BL/6J mice were induced with MOG_{33-55} experimental autoimmune encephalomyelitis (EAE). At the first sign of disease, mice were injected with either PBS, IgG2b isotype control or anti-hnRNP A1-M9 antibodies (100 mcg/mL X 3), which recognize the immunodominant epitope of hnRNP A1 in MS patients. Animals were scored based on disease severity. In contrast to untreated SKNSH cells, cells exposed to T_h17 cytokines showed mislocalization of endogenous hnRNP A1 from the nucleus to cytoplasm, a sign of cellular stress. *In vivo*, animals exposed to anti-hnRNP A1-M9 antibodies exhibited worse disease ($p<0.05$) and more frequent spasticity, a common symptom seen in MS patients. Interestingly, spastin, a known RNA binding partner of hnRNP A1 under normal conditions and causative factor in hereditary spastic paraplegia, was altered in EAE. Specifically, spastin protein levels in the brain were significantly decreased in anti-hnRNP A1-M9 as compared to control, PBS, and IgG animals ($p=0.034$). These data suggest that dysfunctional hnRNP A1 may contribute to MS pathogenesis in a manner similar to other RBPs in neurological diseases. Pro-inflammatory cytokines induced hnRNP A1 mislocalization.

Additionally, anti-hnRNP A1-M9 antibodies worsened disease, led to the development of spasticity in the hind limbs of animals, and altered protein levels of spastin in the brain. This suggests that anti-hnRNP A1-M9 antibodies could play a causative role in the development of spasticity in autoimmune diseases of the CNS, including MS.

Title: Temporal changes in the glial response mechanism in the Cuprizone/Rapamycin model of Multiple Sclerosis

Authors: ***M. MADDIE**[1], D. CHMURA[1], S. LUNN[1], H. BATTAPADY[1], S. MEDICETTY[1], B. TRAPP[2];
[1]Renovo Neural, Cleveland, OH; [2]Cleveland Clin. Fndn., Cleveland, OH

Abstract: Multiple sclerosis (MS) is a chronic immune mediated disease with primary demyelination, formation of glial scars, and progressive neurodegeneration in the central nervous system. The cuprizone-rapamycin (C/R) mouse model is a non-immune mediated, toxic model of MS demonstrating extensive demyelination in both white and grey matter with axonal injury. It has been previously demonstrated that C/R model has robust microglial and astrocytic activation within the corpus callosum by 4 weeks of injury. In this study, we quantified the glial response to injury in the corpus callosum, hippocampus, and cortex to elucidate the region specific temporal response to demyelination. In the corpus callosum, we show that there is approximately 50% loss of oligodendrocytes following 2 weeks of C/R treatment, and almost total loss of oligodendrocytes by 6 weeks. Concurrent with early oligodendrocyte loss we observe a significant increase in microglial activation (Iba1 staining) in the corpus callosum by 2 weeks of C/R (2.7 fold increase in Iba1 when compared to WT control). Peak Iba1 response was seen at 4 weeks of C/R prior to subsequent decrease in staining at 6 and 12 weeks of demyelination (5.7, 5, and 4.5 fold increase in staining compared to WT control respectively). There was no increase in astrocyte marker GFAP at 2 weeks of C/R; however, GFAP activation steadily increases over 4, 6 and 12 weeks of demyelination (5.07, 5.5, 7.6 fold increase in staining compared to WT control respectively). Furthermore, examination of phagocytic macrophages (Mac2) demonstrates a gradual increase in staining over the 12-week paradigm (0.5, 0.8. 1.5 and 2.4. fold increase in staining compared to WT control respectively). In contrast to corpus callosum,

hippocampus and cortex, both of which are demyelinated in this model showed little activation of astrocytes or microglia. These observations demonstrate unique temporal signatures of glial activation in response to C/R treatment. Furthermore, this study highlights a differential glial response to demyelination in white and grey matter. This model can be extremely valuable to study therapeutic interventions that target glial responses in MS.

Title: Ketone body esters as a therapeutic strategy for canavan disease

Authors: *A. P. APPU, P. ARUN, J. R. MOFFETT, J. K. KRISHNAN, A. M. NAMBOODIRI; C-2069, Anatomy, Physiol. and Genet., Uniformed Services Univ. of Hlth. Sci., Bethesda, MD

Abstract: Canavan disease (CD) is a rare neurological disease resulting from genetic defects that manifest as a progressive neurodegenerative disease leading to paralysis and death, usually between 3 and 10 years of age. There is no effective treatment at the present time. CD is caused by mutations in the gene for the enzyme aspartoacylase (ASPA), which produces free acetate from the concentrated brain metabolite *N*-acetylaspartate (NAA). NAA is synthesized in neurons, but ASPA is expressed primarily in oligodendrocytes, and evidence indicates that neurons transfer NAA to oligodendrocytes for acetyl CoA synthesis. Since acetyl CoA is a key building block for myelin lipid synthesis and other critical developmental functions such as gene regulation through histone acetylation, we postulated that the inability to enzymatically catabolize NAA leads to an acetate deficiency in oligodendrocytes during postnatal CNS myelination, resulting in oligodendrocyte death and defective myelin lipid synthesis. Previously we tested the hypothesis that dietary acetate supplementation during postnatal myelination would reduce the severe phenotype associated with ASPA deficiency using the tremor rat model of CD.

Glyceryl-triacetate (GTA), a hydrophobic acetate source, was administered to tremor rats starting 7 days after birth, and administration was continued in food and water after weaning. Significant improvements were observed in motor performance and brain galactocerebroside content in tremor rats treated with GTA. Further, the characteristic brain vacuolation associated with CD was modestly reduced by the treatment. In our efforts to test additional acetate/acetyl CoA sources alone and in combination to improve outcomes further, we have tested a ketone body ester since ketone bodies form a major source of acetyl CoA in the brain during development. The treatment was done essentially as described for GTA, but in the Nur 7 mouse model of CD. Significant improvement in motor functions as measured by rotarod balance was observed in the treated mice. Pathological analysis is in progress to determine if the characteristic vacuolation of ASPA deficiency was reduced. Importance of the ongoing studies lies in the fact that CD has no current treatment and remains a fatal disease which is devastating to the affected families. In contrast to gene therapy, acetate (acetyl CoA) replacement therapy is a simple biochemical approach, which is safe, inexpensive and convenient for use in CD infants.

Title: Neuronal antigen specific T cells modulate CNS inflammation during autoimmunity

Authors: *A. RAYASAM[1,2,3], M. HSU[1,2,3], M. DALLMANN[1], J. KIJAK[1], N. ZINDL[1], M. SANDOR[1,2], Z. FABRY[1,2,3];

Abstract: Multiple sclerosis (MS) is a chronic autoimmune disease of the central nervous system (CNS), which results in axonal demyelination and oligodendrocyte dysfunction. Most of the mouse models of MS such as experimental autoimmune encephalomyelitis (EAE) involve an

immunization to initiate CD4+ T cells to become autoreactive towards myelin. These models mainly evaluate the physical motor dysfunctions observed in MS patients, however, there is strong evidence that higher order neurological and cognitive deficits also occur as well. In order to address the role of anti-neuronal immune responses during MS, we generated transgenic mice using the Nestin specific promoter to localize an EGFP-tagged fusion protein containing ovalbumin (OVA) antigenic peptides in Nestin+ cells (Nestin-OP mice). Using this model, we tested how anti-OVA peptide-specific OT-I (CD8+) and OT-II (CD4+) T cells contribute to disease progression during EAE. Interestingly, adoptive transfer of OT-I and OT-II T cells into Nestin-OP mice significantly reduced EAE clinical scores compared to littermate controls. This suggests that in Nestin-OP mice, the Nestin recognizing T cells become anti-inflammatory or the T cell response steers toward non-motor Nestin+ brain areas. In order to understand the mechanism, we analyzed the cytokine producing potential of the OT-I and OT-II T cells and evaluated the inflammatory and synaptic environment in Nestin+ brain areas in Nestin-OP and littermate mice immunized with EAE. Our results suggest that autoreactive T cells targeted towards non-myelin antigens can influence CNS function independent of EAE score suggesting that therapies targeted towards brain antigen specific T cells deserve more attention for treating MS.

Title: Erythropoietin upregulates brain hemoglobin expression and levels of H3K4me3

Authors: ***N. K. SINGHAL**, K. ALKHAYER, J. SHELESTEK, R. CLEMENTS, E. FREEMAN, J. MCDONOUGH;
Dept. of Biol. Sci. and Sch. of Biomed. Sci., Kent State Univ., Kent, OH

Abstract: Multiple sclerosis (MS) is a neuro-inflammatory and demyelinating disease. Downregulation of neuronal mitochondrial gene expression and activity have been reported in several studies of MS. We have previously shown that hemoglobin-β can signal to the nucleus of neurons and upregulates H3K4me3, a histone mark involved in regulating cellular metabolism

and differentiation. The present study was undertaken to evaluate the effect of erythropoietin (EPO) and upregulation of hemoglobin-β on mitochondrial associated neuroprotection. We found that administering EPO (5000IU/kg of mice intraperitoneally) to mice upregulated brain hemoglobin expression, levels of H3K4me3, expression of complex III, complex V, mitochondrial respiration, and NAA levels. To extrapolate these results to MS, we treated mice with cuprizone (3% in food diet) for six weeks to induce demyelination with or without EPO. Demyelination was measured by magnetic resonance imaging (MRI) and NAA concentration was measured by HPLC as a marker of neuronal mitochondrial activity. We found upregulation of NAA in cuprizone-EPO treated mice as compared to cuprizone only. These data suggests that EPO regulates neuronal mitochondrial activity by modulating H3K4me3 levels.

Title: Intrathecal delivery of primary progressive MS cerebrospinal fluid induces behavioral deficits and spinal cord pathology in mice

Authors: *J. K. WONG, M. ALAHIRI, S. S. SADIQ;
Tisch MS Res. Ctr. of New York, New York, NY

Abstract: Multiple sclerosis (MS) is characterized by inflammatory demyelination, astrogliosis and axonal loss in the CNS, which leads to progressive clinical disability. The majority of patients initially present with relapsing-remitting MS (RRMS), where periods of neurological decline are interspersed with periods of clinical stability. Approximately 10-15% of MS patients have primary progressive MS (PPMS), which manifests as continual progression of clinical disability from disease onset. Although disease-modifying therapies that target the immune system have been effective for RRMS patients, they do not halt disease progression in PPMS patients, suggesting that inflammation may have a more minor contribution to PPMS pathophysiology. Indeed, PPMS lesions tend to contain fewer inflammatory cells and atrophy is predominantly observed in the cervical spinal cord. Currently, there is no animal model that encompasses these characteristics of PPMS.
Here, we sought to develop an animal model of PPMS that exhibits characteristic pathology in the upper regions of the spinal cord. Intrathecal injections of cerebrospinal fluid (CSF) obtained

from either PPMS or RRMS patients were administered to mice. Control mice were injected with saline or CSF obtained from healthy individuals. Mice underwent laminectomies at cervical levels 4 and 5 to expose the underlying spinal cord, and the fluids were injected under the dura mater into the subarachnoid space. Behavioral deficits were assessed by evaluating forelimb reaching and gripping, as well as tail rigidity at multiple time points post-injection. Mice injected with PPMS CSF exhibited significantly impaired forelimb function and increased tail flaccidity as compared to controls, as well as mice injected with RRMS CSF. Mice were perfused at 1 day post-injection (DPI), 3 DPI, and 7 DPI. Spinal cords were post-fixed in 4% paraformaldehyde overnight, cryoprotected in 30% sucrose, then cryosectioned for histological analyses. Spinal cords from mice injected with PPMS CSF exhibited evidence of astrogliosis at all time points examined, as revealed by increased GFAP immunostaining in the dorsal spinal cord. Luxol fast blue staining showed areas of demyelination only in mice injected with PPMS CSF. In contrast, there were no significant differences in Iba-1 immunostaining between treatment groups, suggesting a minimal contribution of microglial activation towards the development of behavioral deficits and spinal cord pathology following intrathecal PPMS CSF injections.

Title: Differences in audio and visual working memory during computerized cognitive rehabilitation in chronic stroke survivors

Authors: *E. M. WALLACK[1], L. P. KELLY[1], A. J. DEVASAHAYAM[1], T. CHATTERJEE[1], M. B. DOWNER[1], J. MCCARTHY[1], G. A. ESKES[2], B. ABRAHA[1], S. M. M. HASAN[1], A. R. CHAVES[1], H. D. WISEMAN[1], J. DAWE[1], M. PLOUGHMAN[1];
[1]Med., Mem. Univ., St. John's, NL, Canada; [2]Dalhousie Univ., Halifax, NS, Canada

Abstract: Background: Persistent deficits in executive function, attention and learning can have detrimental effects on stroke recovery. Working memory involves a number of prefrontal-

parietal networks, which can be sensory modality specific. There is evidence of age related differential decline in audio and visual working memory and Jaeggi and group found some advantage for processing visual material compared to auditory in an n-back working memory task in a group of young and older healthy adults. These differences raise the question of whether visual and auditory working memory would respond the same way to training in a chronic stroke population and differential response to training may impact the outcomes and generalizability to other tasks and functions. Thus, we compared training performance in visual and auditory domains on a similar working memory task in stroke.
Methods: Participants (n=14) were more than 6 months post-stroke from enrolment. Each participant underwent a 10 week (30 minutes, 3 times a week) computerized adaptive dual n-back task training protocol that required them to respond to sequentially presented paired audio and visual stimuli. Measures of stroke severity (National Institutes of Health Stroke Scale; NIH) and cognitive function (Montreal Cognitive Assessment. MoCA) were also collected at baseline. Wilcoxon Signed-ranks tests were used to compare groups and correlation using Pearson's.
Results: Twelve males and 2 females participated (age 65.1 ± 9.7yrs). They had moderately severe stroke (NIH 7.9, SD=4.8) involving the right (n=7), left (n=6) or both (n=1) hemispheres. At week 1 and week 10 participants performed significantly better on audio tasks than visual tasks ($p= 0.001$, $p=0.03$ respectively). Participants showed significant improvement in accuracy over the 10 weeks of training in both audio ($p=0.001$) and visual ($p=0.001$) modalities. Rate of change in auditory and visual performance did not differ during the 10 weeks of training ($p=0.9$). Stroke severity was not correlated with rate of change or with week 1 and week 10 auditory and visual scores. Performance on audio tasks at week 1 was significantly positively correlated with baseline MoCA scores $r(12) = 0.767$, $p=0.01$.
Conclusion: Participants showed improvements over the 10 weeks of training in auditory and visual modalities suggesting learning is feasible after stroke. While participants advanced at a similar pace for both modalities, the auditory advantage persisted at week 10 of training. This auditory advantage may have implications for training generalization and outcome in stroke.

Title: Maximal exercise does not increase brain derived neurotropic factor (BDNF) in chronic stroke survivors: association with resting energy metabolism and peak oxidative capacity

Authors: *L. P. KELLY, A. J. DEVASAHAYAM, E. M. WALLACK, B. ABRAHA, J. MCCARTHY, M. B. DOWNER, S. M. M. HASAN, F. A. BASSET, M. PLOUGHMAN;
Fac. of Med., Mem. Univ., St. John's, NL, Canada

Abstract: Background: Brain derived neurotrophic factor (BDNF) plays a crucial role in the recovery of the injured brain after stroke. Serum BDNF is considered a surrogate biomarker for brain plasticity. Furthermore, the beneficial effects of exercise on peripheral energy metabolism may be mediated through BDNF signaling. The purpose of this study was to determine the effect of maximal exercise on serum BDNF and its association with resting and maximal oxidative capacity.
Methods: Eighteen non-diabetic chronic stroke survivors (>6months) with no significant contraindications to maximal graded exercise testing (GXT) were recruited. Participants were first subjected to a resting metabolic rate measurement using a metabolic cart and flow-through canopy to determine whole-body resting energy production (EP) and the relative contributions from lipid and glucose oxidation (Lox and Gox, respectively). On a separate day, participants had resting blood samples drawn just prior to and immediately after a GXT for later analysis of serum BDNF. The GXT was performed on a total body recumbent stepper to exhaustion while heart rate (HR), ventilation (VE) and expired air were sampled for rate of oxygen consumption (VO_2) and carbon dioxide production (VCO_2) using a facemask and metabolic cart. Serum BDNF was compared pre and post-exercise using t-test; and correlation of variables using Pearson's.
Results: Participants (11F, 7M) were 68±9 years of age, and 34±25 months post-stroke. Although BDNF levels were relatively high at rest prior to exercise (30.7±19.2 ng/ml), post-exercise values were not significantly different from resting (33.1±16.1; p=0.56). A very low oxidative capacity was observed during the GXT (16.1±5.5 ml min^{-1} kg^{-1}), however, resting energy metabolism was within ranges expected based on age and gender (EP=1.0±0.2 kcal min^{-1}; Lox=68.7±22.6 %; Gox=14.3±21.6%). There were no significant correlations between resting or post-exercise BDNF and resting or maximal oxidative capacity.
Conclusion: The current analysis suggests that exercise does not increase serum BDNF concentrations beyond that observed at rest in chronic non-diabetic stroke survivors. People with stroke who have very low oxidative capacity may have blunted BDNF response to maximal exercise. Our findings further elucidate the usefulness of serum BDNF as a marker of plasticity.

Title: Can circulating bdnf levels discriminate high from low impairment in chronic stroke survivors?

Authors: *B. ABRAHA, E. M. WALLACK, L. P. KELLY, A. J. DEVASAHAYAM, T. CHATTERJEE, S. GRANTER-BUTTON, J. MCCARTHY, M. PLOUGHMAN;
Med., Mem. Univ., St. John's, NL, Canada

Abstract: Background: Stroke rehabilitation aims to restore lost cognitive and motor skills which requires neuroplasticity. Recent research has implicated Brain-Derived Neurotrophic Factor (BDNF) as a precursor of neuroplasticity. There is debate whether or not peripheral (serum) BDNF could be a useful biomarker of recovery and plasticity in stroke. We investigated whether serum levels of BDNF were related to measures of physical and cognitive neurological impairment in stroke survivors.
Methods: All participants (n= 35) suffered a haemorrhagic or ischemic stroke greater than 6 months. They performed a graded maximal exercise test, with blood collection before and after. We used National Institute of Health Stroke Scale (NIH) to measure the global level of neurological impairment; Chedoke-McMaster stage of combined leg and foot recovery to measure degree of motor recovery and cognition using Montreal Cognitive Assessment (MOCA) and Ravens Matrices (test of fluid intelligence). Serum BDNF concentrations expressed in ng/ml, were determined using manufacturer's protocol (R&D Systems ELISA). The sample was split into high (>5 NIH) and low (≤ 5) impairment compared using ANOVA. BNDF levels pre and post exercise were compared to outcomes using correlation analysis.
Results: There were 23 males, 65.1 years of age ($\pm$9.9) and 12 females, 65.5 years of age ($\pm$8.8). Patients with greater stroke severity (>5 NIH) had higher serum BDNF [$F(1, 33) = 10.157$, $p = 0.003$]. In addition, serum BDNF fold-change ($R=0.44$; $p< 0.05$), and BDNF raw change ($R=0.40$; $p<0.05$) were significantly correlated with fluid intelligence (Raven's Matrices). Global cognition (MOCA) was also significantly correlated with baseline BDNF ($R=-0.41$, $p <0.05$). While physical impairment (Chedoke-McMaster) was not significantly related to baseline serum BDNF or the responsiveness of BDNF.

Conclusion: Paradoxically, patients with greater stroke severity had higher resting serum BDNF whereas the change in BDNF (as a result of exercise) was related to fluid intelligence. Also individuals with greater baseline levels of BDNF had lower global cognition. These findings suggest that the relationship between serum BDNF and neuroplasticity is complex but in this sample, BDNF was a more robust marker of cognitive rather than physical impairment.

Title: Is BDNF response to maximal exercise associated with performance in cognitive rehabilitation training in chronic stroke survivors?

Authors: *H. D. WISEMAN, M. B. DOWNER, B. ABRAHA, E. M. WALLACK, T. CHATTERJEE, L. P. KELLY, A. J. DEVASAHAYAM, A. R. CHAVES, J. MCCARTHY, M. PLOUGHMAN;
Mem. Univ., St. John's, NL, Canada

Abstract: Background: Cognitive recovery post stroke is highly variable, and currently there are few ways to predict response to cognitive training in chronic stroke survivors. Increased circulation of key neurotrophic factors such as brain derived neurotropic factor (BDNF) may be a key link to cognitive recovery post stroke. Several exercise paradigms have been shown to up-regulate circulating levels of BDNF. It is currently unclear whether differences in BDNF levels from exercise are associated with differences in response to cognitive training in chronic stroke survivors. **Methods:** All participants experienced a haemorrhagic or ischemic stroke more than 6 months pre-enrollment. Participants underwent a 10 week intervention consisting of 30 minutes of exercise followed by 30 minutes of cognitive training, 3 times a week. A graded maximal fitness test was performed before the intervention, with blood collection before and after

exercise. The blood was left to coagulate for 30 minutes, centrifuged for 10 minutes at 1500rpm and plasma was extracted for later analysis using a BDNF ELISA kit. Cognitive training consisted of a computerized sequential adaptive dual n-back task (N-IGMA). The cognitive score was calculated by combining both level and accuracy of the task. Classification of responders and non-responders was determined by averaging peak working memory capacity scores. Participants who improved 35% or greater from their week 1 score were classified as "responders" and those who did not were coded as "non-responders". **Results:** Responders (n=6) had a mean age of 64.2 (SD±10.72) and non-responders (n=5) had a mean age of 64.6 (SD±9.017). Pre-exercise BDNF levels between responders (M=51.86, SD±19.37) and non-responders (M=72.68, SD±28.07) were not significantly different (F=2.116, p=0.180). Responders mean change in BDNF (20.51 ng/mL (SD±6.54)) as a result of exercise is significantly higher than BDNF than in non-responders (-11.05 ng/mL (SD±12.90)) (F=5.305, $p<0.05$). **Conclusions:** Our findings suggest that acute change in BDNF levels due to exercise may indicate ability to respond to cognitive training in those living with chronic stroke. Individuals who demonstrate a greater up-regulation of BDNF through exercise may be able to use the higher concentration of factors to help improve in cognitive performance soon thereafter; whereas individuals with less up-regulation may have less ability to respond to cognitive training. Further rehabilitation programs could use serum BDNF levels as a way to determine those who are more likely to respond to paired exercise-cognition training post-stroke.

Title: Anti-inflammatory activity of adiponectin function on BBB after intracerebral hemorrhage

Authors: *X. YANG[1], H. JANG[2], Y.-J. KIM[3], I.-Y. CHOI[3], S.-H. LEE[4], B.-W. YOON[4]; [1]The neurology depertment, The Seoul Natl. Univ. Hosp., seoul city, Korea, Republic of; [2]Dept. of cardiology, [3]Col. of Med. and Neurosci. Res. Inst., [4]Dept. of Neurol., Seoul Natl. Univ., seoul, Korea, Republic of

Abstract: *Background* Obesity is the increased prevalence of diseases. Adipose tissue associated with obesity secreted many cytokines, such as adiponectin, one of the most abundant adipokine

with anti-inflammatory effects. The clinical significance of adiponectin in cardiology has been extensively identified, but in stroke remains controversial. *Method and results* To investigate the role of adiponectin in the intracerebral hemorrhage (ICH), we subjected collagenase-induced male imprinting control regions (ICR) mice of ICH before adiponectin treatment. ICR mice exhibited large hematoma and edema after ICH, however, adiponectin preconditioned group (APN-ICR) significantly attenuated these damages. Furthermore, APN-ICR mice showed decreased the inflammation and MMP activation. In culture of astrocytes stimulated by hemolysate to mimic the hemorrhage situation, inflammatory activations were significantly reversed by adiponectin. Endothelia cells, which were exposed to conditioned media from astrocytes stimulated by hemolyste, significantly increased expression tight junction proteins. However, adiponectin abolished disorganization of them. *Conclusions* Taken together, these results suggest that adiponectin exerts an important neurovascular protective effects on mice of ICH and support the mechanism of crosstalk between reactive astrocytes and endothelia wherein adiponectin inhibiting the inflammatory activities and enhance the blood-brain barrier.

Title: Activity-dependent regulation of neurogenesis after stroke

Authors: ***H. LIANG**[1], S. T. CARMICHAEL, 90066[2];
[1]Neurol., Univ. of California Los Angeles Dept. of Neurol., Los Angeles, CA; [2]UCLA, Los Angeles, CA

Abstract: Stroke is the leading cause of adult disability. Post-stroke neurogenesis has been implicated in repair and functional recovery in stroke; however the cellular and molecular mechanism that regulates neurogenesis after stroke remains unclear. Although activity has been shown to regulate neurogenesis during development in normal brain, how modulation of activity affects neurogenesis after stroke is not fully elucidated. In this study, we employed forced use of the paretic forelimb that mimics constraint-induced movement therapy (CIMT) as a physical

modulation of activity after stroke. We found that forced use of paretic forelimb contralateral to the stroke site enhanced neuroblast migration and neural progenitor proliferation in the peri-infarct cortex at post-stroke day 14; neuronal differentiation was increased on post-stroke day 60.Interestingly,when forced use was performed in the hindlimb contralateral to the stroke site, proliferation and neuroblast migration to the peri-infarct cortex was largely abolished and long term neuronal differentiation significantly decreased with a surprising substantial increase in glial differentiation. These data suggest that activity-induced neurogenesis after stroke is circuit specific and is dependent on regions of modulation. To further demonstrate the role of activity in a cell type specific manner, we utilized the Designer Receptors Exclusively Activated by Designer Drugs (DREADD) as a pharmacological approach to modulate both neuronal and glial activity in the peri-infarct region. We found that post-stroke neuroblast migration significantly increased when cortical CaMKII-expressing neurons were activated with DREADD stimulation. Interestingly, selective use of the inhibitory DREADD in astrocytes decreased post-stroke neuroblast migration. These data suggest that post-stroke neurogenesis is modulated through both neuronal and glial activity in the peri-infarct regions. Finally, neuronal tracing techniques including BDA labeling and rabies-virus based monosynaptic tracing are ongoing to address whether activity regulates integration of adult-born neurons into the injured cortex circuitry.

Title: Customary exercise prevents the poststroke memory dysfunction by constitutive elevation of hippocampal BDNF

Authors: *N. HIMI[1], N. OKABE[1], E. NAKAMURA-MARUYAMA[1], H. TAKAHASHI[2], T. KOGA[2], K. NARITA[1], O. MIYAMOTO[1];
[1]Physiol. 2, Kawasaki Med. Sch., Kurashiki Okayama, Japan; [2]Rehabil., Kawasaki Univ. of Med. Welfare, Kurashiki, Okayama, Japan

Abstract: Exercise in the poststroke stage is known to facilitate the recovery from memory and motor dysfunction. We have showed that the spatial memory function was recovered by the elevation of hippocampal brain-derived neurotrophic factor (BDNF) only in the early stage after

stroke. In the present study, we further investigated the preventive effects of customary exercise on memory and motor impairment induced by stroke. In this study, two different stroke models were employed to confirm the preventive effect on different symptom and severity. Microsphere (MS) embolism model showed spatial memory dysfunction and internal capsule infarction model showed motor dysfunction. Rats were forced to run on a treadmill with mild strength (15m/min, 30min/day) for 7 days as the exercise (Ex group). At the 8th day after the beginning of exercise, 3,000 particles of MSs (ϕ45μm) were injected via right internal carotid artery of rats (MS group) or photosensitive dye was injected into artery and 488 nm laser was irradiated to internal capsule by optic fiber (IC group). Non-exercise group (NE group) and sham operated groups were also examined as control groups. The Morris water maze test (MS group) and rotarod test (IC group) were performed at 8 days after the onset of stroke. BDNF concentration in transected hippocampus (MS group) and thalamus (IC group) were measured at 0, 4, 7 days before and 4 and 7 days after the onset of stroke by ELISA.
BDNF concentration was elevated by exercise and decreased after the completion of exercise in both MS- and IC- Ex group. The memory functions in the MS-Ex group was significantly improved compared with the MS-NE group. IC-Ex group showed no significant motor function recovery.
These results suggest that the constitutive BDNF elevation in hippocampus by customary exercise might prevent the spatial memory dysfunction after stroke.

Title: Kinect-based upper extremity training is effective for individuals with stroke: Outcomes and participants' perspective

Authors: ***W.-W. LIAO**[1], S. MCCOMBE WALLER[1], R. FELDMAN[1], J. WHITALL[1,2]; [1]Physical Therapy Rehabil. Sci., Univ. of Maryland Baltimore, Baltimore, MD; [2]Univ. of Southampton, Southampton, United Kingdom

Abstract: The low-cost virtual reality system such as Microsoft Kinect has become an increasingly popular tool for continued stroke rehabilitation outside of traditional rehabilitation. Despite its popularity, the usability, therapeutic methods and participants' perspective towards use of computer-based training such as the Kinect system remains largely unaddressed. The purpose of this study was to investigate the effectiveness of Kinect-based upper extremity (UE) training on arm impairments and functional performance in individuals with stroke in order to determine its applicability in a clinical/home setting. In addition, we examined stroke survivors' experience regarding Kinect-based training. **Methods:** Ten individuals (mean age 62.5±9.06 years) with chronic hemiparesis (7Lt,3Rt) were recruited from the local community. Subjects participated in Kinect-based UE training three times a week with a target duration of 4-5 weeks. To simulate the home/clinic environment, the therapist guided participants at the initial three sessions, then withdrew input for the remaining of the training including interface with the system to start the exercise program. Outcome measures included Fugl-Meyer UE assessment (FM-UE), Wolf Motor Function Test (WMFT), Active Range of Motion for shoulder and elbow (AROM), the hand function portion of Stroke Impact Scale (SIS) and Confidence in Arm and Hand Function (CAHM). Participants' experience and feedback toward use of Kinect UE training was assessed using a structured questionnaire and a semi-structured interview. **Results:** Significant improvement was found in FM-UE, WMFT, AROM as well as the Hand function of SIS post-training ($p<.05$). Eight out of 10 individuals reported increased use of the paretic arm in daily activities in the interview. Ninety percent of individuals found the training engaging and easy to follow reporting that the visual and auditory feedback were useful in training. All recognized the importance of the individualized modification made by the therapists at the beginning of training. **Conclusion:** We demonstrated that four weeks of Kinect-based UE training was able to provide clinically important and self-perceived improvements in arm function for chronic stroke survivors. Individualization of the Kinect exercises by therapists, at least in the first few sessions, appears important for use in the clinics/home setting.

Title: Stroke induced brain morphological changes and the influence of physical exercise

Authors: S. GULL[1], S. SCHMIDT[1,2], K.-H. HERRMANN[3,2], C. FRAHM[1], J. REICHENBACH[3,2], C. GASER[1,2,4], *O. W. WITTE[1,2,5];

Abstract: *Objective:* Stroke represents one of the leading causes of adult disability and recovery is highly challenging for most survivors. Early restorative therapies like appropriate physical exercise are shown to improve the outcome in motor function. It is believed that exercise improves spontaneous intrinsic mechanisms of recovery but how the brain reorganize following stroke and how this reorganization is influenced by therapies is not fully understood. Here we used a longitudinal approach to analyze the influence of acrobatic training on dynamic changes of brain morphology following motor cortex lesions in young adult rats by employing magnetic resonance imaging (MRI) and deformation-based morphometry (DBM). *Method:* Experimental stroke was induced in the right motor cortex of male Wistar rats (3 months old) by Photothrombosis (PT). One group of animals was subjected to daily acrobatic training starting immediately following stroke for 8 weeks with slowly increasing difficulty whereas the remaining animals recovered spontaneously. T2-weighted 3D MR images were acquired longitudinally at baseline and 1, 2, 4, 8 weeks following PT and processed by DBM. The performance of paw placement during locomotion and the outcome of recovery were analyzed by using the ladder rung walking task. *Results:* Stroke impaired the performance of contra-lesional paws. Our acrobatic training regime did not influence the dynamic of lesion volume but it significantly improved the outcome of recovery. DBM analysis revealed a pattern of training independent structural reorganization of the brain. Most of these changes were restricted to the initial recovery phase and the lesioned hemisphere whereas the training enhanced their amplitudes but not overall dynamics. In addition, acrobatic training evoked structural changes in a second cluster of brain areas including the putamen and the lesion surrounding cortex. *Conclusion:* Acrobatic training improves the final outcome of motor function recovery after motor cortex stroke - reflected by whole brain structural reorganization which is most prominent in the early recovery phase. Further analyses are needed to understand the recovery process as a whole and to explore which specific types of plasticity takes place in different remote areas.

Title: Short bouts of exercise before ischemic stroke ameliorate behavioral and histological outcomes by enhancing angiogenesis

Authors: *S. PIANTA, H. NGUYEN, S. MASHKOURI, D. AUM, X. KAYA, N. TAJIRI, S. ACOSTA, J.-Y. LEE, C. V. BORLONGAN;
Dept. of Neurosurg. and Brain Repair, Univ. of South Florida Col. of Med., Tampa, FL

Abstract: Stroke remains a significant unmet clinical need with limited therapeutic options. Exercise has been the shown to afford therapeutic benefits in stroke patients, but the mechanism of action is still unknown. The peculiar feature of ischemic stroke is the interruption in brain blood circulation, therefore finding strategies to maintain the potency of the cerebrovasculature may provide a therapeutic effect against stroke. The present study assessed the effects of short bouts of exercise prior to experimental stroke induction, and characterized in vivo the cerebral blood flow, concomitant motor functions, and immunohistochemical markers of angiogenesis and vasculogenesis. Initially, adult Sprauge-Dawley rats were exposed once to short bout of exercise (30-minute or 60-minute of forced running wheel), then they were subjected to transient intraluminal occlusion of the middle cerebral artery (MCAo). Separate cohorts of non-exercised stroke rats served and no stroke rats served as controls. Cerebral blood flow (CBF) was evaluated by laser Doppler at baseline (prior to MCAo), during MCAo, and during reperfusion. Behavioral test using the elevated body swing test was conducted at baseline, day 0 (day of stroke), and at days 1 and 3 after stroke. Results revealed significant elevations of CBF during reperfusion in 60-minute exercised rats compared to 30-minute exercised rats and controls. Moreover, the animals that received 60-minute exercise displayed improved motor performance than 30-minute exercise and non-exercised rats. Histological analysis revealed that exercised rats exhibited a reduction of the infarct size area and increased number of the live cells in the peri-infarct area, specifically this trend follows the duration of the exercise. Immunofluorescence staining intensity revealed increased levels of angiogenesis markers Ang-2 and VEGFR-2 and EPC marker CD34+ in exercised groups compared with controls. These results suggest that prophylactic exercise improves cerebrovascular integrity and function, in that exercise-induced facilitation of angiogenesis may attenuate the debilitating stroke outcomes.

Title: Effects of repetitive passive ankle stretch applied with a pneumatic robot on soleus h-reflex excitability

Authors: *S. NOBLE[1,3,4], G. E. P. PEARCEY[1,3,4], C. QUARTLY[5], P. E. ZEHR[1,3,2,4]; [1]Exercise Science, Physical & Hlth. Educ., [2]Div. of Med. Sci., Univ. of Victoria, Victoria, BC, Canada; [3]Rehabil. Neurosci. Lab., Victoria, BC, Canada; [4]Intl. Collaboration On Repair Discoveries, Vancouver, BC, Canada; [5]Collaborative Spasticity Program, Queen Alexandra Hosp., Vancouver Island Hlth. Authority, Victoria, BC, Canada

Abstract: Neurotrauma can result in spasticity which impairs motor control and walking ability. Spasticity is characterized by hyperactive stretch and electrically evoked Hoffmann (H-) reflexes. Therapeutic stretching is used in spasticity management, but long-term physiotherapy services are expensive and inaccessible to the majority of spastic patients. Commercial devices that provide stretch without a therapist have recently been developed and may be useful, however quantified effects on spinal cord excitability are unknown. H-reflex excitability in 13 neurologically intact participants (9 male and 4 female; age 19-28) was assessed after 30 minutes of gentle passive dorsiflexion stretching induced by a pneumatic robot. H-reflexes evoked in the soleus muscle and ankle range of motion were examined before, during, and after gentle stretch. The pneumatic robot moved the ankle through 91.9 ± 7.3% of maximal active range of motion. The stimuli delivered to evoke H-reflex recordings occurred at ankle joint angle of 88.8 ± 7.5^{o}, corresponding to 77.6 ± 8.2% of active range of motion. H-reflex amplitudes were significantly different (52.4 ± 50% change; $p<0.05$) between pre-stretching and the mid-session sampling in 9 participants and between pre- and post-stretching in 11 of 13 participants (37.1 ± 37.3% change).

These data suggest that 30 min of pneumatic robot-induced gentle passive stretching at the ankle can significantly alter spinal cord reflex excitability.

Title: Dysfunctional Notch 3 signaling inhibits the mediation of beneficial effects of physical activity and enriched environment on adult neurogenesis in a transgenic CADASIL mouse model

Authors: *C. KLEIN[1], S. SCHREYER[1], F. E. KOHRS[1], P. EL HAMOURY[1], A. PFEFFER[1], T. MUNDER[1], F. EHRET[2], G. KEMPERMANN[2], B. STEINER[1];
[1]Charité Neurol., Berlin, Germany; [2]Ctr. for Regenerative Therapies Dresden, Dresden, Germany

Abstract: The theory of a "vascular niche" related to adult neurogenesis describes the interaction of neural stem or precursor cells and endothelial cells of cerebral blood vessels. The hippocampus, where new neurons are generated for integrating new spatial memory, is a highly vascularized niche. For CADASIL (cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy), the most common hereditary form of stroke and vascular dementia, a dysregulated adult hippocampal neurogenesis has been suggested as a potential mechanism for the manifestation of dementia. Previous work has shown that mice overexpressing Notch 3 with a CADASIL mutation display reduced cell proliferation and survival of newborn neurons at 12 but not 6 months of age. In transgenic controls overexpressing wild type Notch 3, cell proliferation and survival of newborn neurons are already reduced at 6 months. It has been demonstrated that Notch 3 is expressed in hippocampal precursor cells and maturing neurons and that Notch 3 signaling negatively regulates precursor cell proliferation. This suggests a loss-of-function effect in CADASIL. Here, we aimed to further elucidate the role adult hippocampal neurogenesis plays in CADASIL and how neurogenesis is regulated by Notch 3 as part of the vascular niche. Adult neurogenesis can be robustly stimulated by physical exercise and environmental enrichment. To also investigate the influence of such stimuli on a dysregulated hippocampal neurogenesis in the CADASIL mouse model, animals (female, 8-12 weeks old) were housed in standard (STD), environmentally enriched (ENR) or running wheel cages (RUN) for either 28 days or 6 months. Two transgenic mouse lines were used: Tg88+ mice overexpress the mutant form of the gene and develop CADASIL, while the Tg129+ mouse line overexpresses wild type Notch 3 and serves as control for the mutation. Adult neurogenesis is

reduced in older but not yet in younger Tg129+ mice. RUN and ENR failed to stimulate neurogenesis in both transgenic mouse lines. In Tg88+ mice, this is probably due to decreased physical activity, because they ran far less than controls. In contrast, Tg129+ mice were even more active during 28 days of physical exercise than controls but still lack stimulated neurogenesis. Older CADASIL mice displayed enhanced gliogenesis in the hippocampus indicating an increased inflammatory response due to frequent strokes at this stage. This was reduced by six months of RUN but not ENR. The present results suggest that the beneficial effects of physical exercise on cell proliferation and of enriched environment on cell survival in the hippocampus may depend on Notch 3 signaling.

Title: Post stroke bimanual performance relates to corpus callosum properties

Authors: *A. M. AURIAT[1], J. LAU[2], J. K. FERRIS[1], J. L. NEVA[1], L. A. BOYD[1];
[1]Physical Therapy, [2]Univ. of British Columbia, Vancouver, BC, Canada

Abstract: Background: White matter fractional anisotropy (FA) of corpus callosum (CC) tracts relates to post-stroke motor outcome. However, we do not understand how regional differences in CC structure relate to bimanual motor performance after stroke.
Methods: Diffusion weighted resonance imaging was obtained from all participants. Interhemispheric connections from 5 CC subregions (I-anterior, II-anterior midbody, III-posterior midbody, IV- isthmus, V-splenium) were traced by placing a single seed ROI in the medial midsagittal section of the CC. Tracts were generated from the ROI with constrained spherical deconvolution tractography, and FA values for the entire track were obtained. All diffusion processing was completed in ExploreDTI.
A KINARM robot was used for 3 upper-limb assessments: 1) Arm Matching: the robot moved participants' non-dominant/paretic hand to a target positions and the participant had to mirror match the location with the opposite hand. 2) Object-Hit: participants hit virtual balls moving

towards them with virtual paddles attached to each hand. 3) Object-Hit and Avoid: cognitive demand of the Object-Hit task was increased, by requiring participants to hit two target shapes while avoiding all others. Results are displayed as mean ± SD. Correlations were considered significant at a corrected p-level of < 0.01.
Results: We assessed 25 neurologically intact (NI) individuals (age: 61.7 ±9 .6), and 25 individuals (age: 65.6 ± 8.1) at least 6 months (74.6 ± 14.1 months) following a stroke. Arm Matching: Limb matching error was greater following stroke than in the NI group (8.5 ± 4.5 vs 5.6 ± 2.0%, $p = 0.018$). No CC regions related to performance in arm matching for either group ($p \geq 0.075$). Object Hit: Stroke participants hit significantly fewer targets (177.4 ± 51), than the NI group (251.5 ± 35; $p < 0.001$). For the NI group, total hits correlated with FA of CC region II ($r = 0.527$, $p = 0.007$), but this relationship was not significant for the stroke group ($r = 0.422$, $p = 0.035$). Hit and Avoid: Post-stroke participants made fewer target hits (106.2 ± 25) compared to the NI group (149.3 ± 23, $p < 0.001$). Total hits correlated with CC region II ($r = 0.533$, $p = 0.006$) in the NI group but with regions III ($r = 0.505$, $p = 0.009$) and V ($r = 0.511$, $p = 0.008$) of the stroke group.
Conclusion: Post-stroke bimanual motor function is impaired, and does not relate to the FA of the CC region II (motor). However, at least in the more demanding bimanual task, CC regions III (sensory) and V (temporal/occipital) relate to post-stroke motor performance. Suggesting that bihemispheric sensory and visual processing contributes to bimanual post-stroke motor performance.

Title: Robot-assisted mechanical therapy protects against stroke-induced skeletal muscle injury

Authors: *C. L. RINK, M. BALCH, H. HARRIS, S. GNYAWALI, C. K. SEN, S. KHANNA; Surgery, The Ohio State Univ. Wexner Med. Ctr., Columbus, OH

Abstract: The scientific study of post-stroke physical therapy is challenged in part by a lack of objective tools available to researchers for systematic pre-clinical testing. Here we report first outcomes having developed a Robot-Assisted Mechanical Therapy (RAMT) device to objectively address the significance of mechanical physiotherapy on post-stroke outcomes. Male Wistar rats were subjected to the intraluminal thread method of middle cerebral artery occlusion (MCAO) for 90 minutes. Following stroke, rats received up to 14 days of RAMT therapy (0.5N @ 1Hz over 10mm of stroke-affected gastrocnemius for 30min, RAMT+) or matching anesthesia without therapy (RAMT-). The effects of RAMT on post-stroke sensorimotor function were quantified, and stroke-affected gastrocnemius muscle was evaluated. Compared to controls, RAMT+ significantly improved post-stroke sensorimotor function as measured by AnyMaze^{TM} and TreadScan^{TM} software scoring systems. Examination of mechanotransduction-sensitive pathways revealed RAMT increased brain-derived neurotrophic factor (BDNF) and decreased myostatin expression in stroke-affected gastrocnemius muscle. Outcomes establish a reproducible model to quantitatively assess mechanical therapy for sensorimotor recovery following neurological injury and provide first evidence to support RAMT improvement in post-stroke sensorimotor function.

Title: Delayed administration of citalopram is associated with long-lasting motor improvements and promotes brain remodelling in an experimental model of stroke

Authors: S. CHEN[1], L. BENNET[2], *A. L. MCGREGOR[3];

Abstract: There is growing clinical and experimental evidence that functional recovery after stroke may be modulated by concomitant CNS medication. Recent evidence suggests treatment with antidepressants may promote, while anti-psychotics may suppress functional recovery. However, the timeframe in which these pharmacological agents can influence stroke recovery is not well understood. This research investigated whether delayed administration of citalopram, used clinically in the management of post-stroke depression, could improve functional recovery in an experimental mouse model of stroke.
CSF1-EGFP mice were subjected to 45 min. occlusion of the middle cerebral artery under isoflurane anaesthesia. Animals were administered citalopram (1mg/kg/day, n=13) or saline (n=12) 3 days after stroke for 4 weeks. Neurological deficits and functional performance in the sticky label removal, staircase, and corridor tests were assessed at 1, 2, 4, 6, and 8 weeks post-stroke. 30μm brain cross-sections were processed for thionin and luxol fast blue histology, and immunofluorescence analyses with GAP43, MAP2, and Cyclin D1.
Ischaemic stroke produced a unilateral impairment in food retrieval in the staircase test. Citalopram-treated animals showed significantly improved impaired forepaw use 1, 2, and 6 weeks post stroke compared to controls in staircase test ($p>0.05$). Improved skilled motor function in citalopram-treated animals was associated with reduced EGFP expression ($p<0.05$) and preservation of white matter preservation in the ipsilateral cortex and corpus callosum respectively. Triple-label immunocytochemistry showed an inverse relationship between the level of EGFP expression relative to MAP2, Cyclin D1, and GAP43 expression in the peri-infarct striatum and cortex.
Administration of citalopram 3 days after stroke reduced brain inflammation and produced long lasting improvements in functional performance. Reduced brain inflammation correlated with increased white matter integrity and upregulation of markers of brain remodelling, suggesting that tissue reorganisation contributes to improved functional recovery in these animals. The extended therapeutic window observed in this study indicates that administration of citalopram in the sub-acute phase may be a useful treatment strategy for the large number of stroke patients who experience delayed hospital admission.
